The whole subject of the design and construction of earth dams reverts to the fundamental fact that the engineers in charge must have a thorough understanding of the nature of the materials which are to be used in the dam, and appreciate the practical limitations of these materials when used in large masses, either alone or mixed with each other in various proportions. This knowledge should be obtained and applied before the dam is built.

A hydraulic-fill dam should be composed of materials which, when finally in place in the structure, will be practically water-tight throughout a portion of the cross-section. If this water-tight portion is to be confined to the central part of the dam, it is believed that it will be a distinct advantage to have the up-stream prism of the dam as compact and nearly water-tight as is reasonably possible. This prism will then be more stable in itself and, due to its added weight and solidity, will

Mr. Swanitz.

offer greater resistance to sliding and settlement both during construction and afterward. The prism of the dam on the down-stream side of the core-wall should be of a comparatively porous nature in order to allow an easy means of escape for the water which drains horizontally from the core during construction, and also for any water which may appear later as a more or less permanent seepage through the dam. This down-stream prism plays an important part in the ultimate resistance of the dam, both against sliding and also in case the structure should be overtopped at any time during construction, or later. For these reasons it will be found advantageous to use a rock-fill toe of more or less generous proportions, as well as a heavy covering of a large rock rip-rap over the entire down-stream face. In important structures an ample freeboard should also be provided.

The dam must have slopes sufficiently flat to insure the stability of the structure under all conditions of saturation from the water in the reservoir. In most cases a slope of 3 to 1 up stream and 2 to 1 down stream will insure this, if the correct materials are used and if they are correctly placed.

The spillway of an earth dam must receive careful consideration as to its capacity, location, and method of construction, as it is the final safeguard against destruction in case of an unprecedented flood occurring with a full reservoir. The dam should be built so that no large cracks will form and no undue settlement will occur after completion. Core material must be of such a nature and placed so that it will drain and solidify while construction is in progress, at least to a point where it will not readily transmit full pressure as a hydraulic medium from the core material at a higher elevation.

These conditions regarding the core clearly indicate that one made of pure clay in which much of the material is very fine-grained should not be used, as it will undoubtedly form a mass of supersaturated liquid mud if placed at the ordinary rate of hydraulic-fill construction. This occurred at the Calaveras Dam. The core should be composed of a mixture of clay, sand, and gravel, the percentage of clay being just sufficient to fill the voids. Such a core will become very stiff and resistant on drying out; moreover, it will drain itself and solidify sufficiently during construction to prevent the transmission of hydraulic pressure or undue settlement in the finished structure.

Mr. Hazen points out that more rapid and thorough drainage and consolidation of the core material will be obtained by wasting the finest particles of clay, and the writer agrees with this, especially where the core material consists of an excess of clayey matter. This in effect amounts to abolishing the method of maintaining a comparatively still, standing, "summit pool", which allows of nearly complete deposition of all hydraulicked material. This fact has been appreciated and used

Mr. Swanitz. by some engineers in hydraulic-fill construction for a number of years, notably in the regrading at Seattle, Wash., and other work.

In cases where considerable doubt exists as to the correct method of building an earth dam (especially one of great height, with an important function to perform) the dry-fill method should be adopted without hesitation. This is certainly the case at Calaveras.

The tests and experiments given by Mr. Hazen would no doubt be of some value in furnishing a rough preliminary idea of the stability that might be expected of a structure built with certain materials in various combinations. However, it is not believed that in the majority of cases it is necessary to go to this trouble.

Mr. Justin. JOEL D. JUSTIN,* M. AM. SOC. C. E. (by letter).—This paper proves conclusively what many engineers had before only dimly realized, namely, that the inclusion in hydraulic-fill dams of the finer particles of certain clays, introduces an element of danger which should be eliminated either by the exclusion of such minutely fine particles or else by the addition of especially heavy toe fills of rock or other stable material to counteract the semi-liquid pressure of the core.

It appears to be quite generally recognized that the use of a central pool is an essential feature of the process of constructing an earth dam by the hydraulic sluicing method. Of course, a large central pool with a long period of settling is an essential feature if it is considered necessary to deposit from the water all or nearly all the suspended particles. Mr. Hazen, however, has shown that this is undesirable, as it leads to an unstable condition of the core. He advocates a great reduction in the dimensions of the central pool from those in current use, so that the period of settling will be shortened and the finest material not deposited.

The writer, however, raises the question: Why use a central pool at all? The fine impervious material will do the most good at the up-stream face and may be placed there by keeping the sluicing trestles at or near the down-stream face and allowing the soil-laden water to be discharged in an up-stream direction. Fig. 28, which is diagrammatic merely, indicates the various stages in the construction of an earth dam by this modified hydraulic-fill method. The material at the down-stream face is kept heaped up so that no water flows over it. As the water is discharged from the trestle, a great deal of the coarser material will be deposited in the vicinity of the trestle.

The slope is built up so that the finer material, with the water carrying it, will flow up stream. At the up-stream face a low brush dam is maintained, such that there is a small pool near the up-stream face, say, 1 ft. or 2 ft. deep and 15 ft. wide. The surplus water bearing the finest material is allowed to flow over the brush dam and down the up-

* Winston-Salem, N. C.

stream face. If plenty of brush is used, this practice will not cause much trouble from erosion, as the brush protects the face quite effectively. If brush is not available, baffle-boards may be used, and the surplus water and the rejected fines disposed through sluices or pipes. Mr. Justin.

The condition then existing is quite analogous to that illustrated by Mr. Hazen in Fig. 10, where the central pool was contracted to very slight dimensions, resulting in the deposit of material having an effective size of 0.01 mm., which material soon became stable.

With the small pool mentioned, located at the up-stream face, the material deposited would soon become stable. In fact, it would be entirely impossible to use a large pool and deposit a fine material which did not soon become stable, for a brush dam or other slight barrier at the up-stream face would not be strong enough to retain such a semi-liquid fill which would at once break out and flow down the up-stream face.

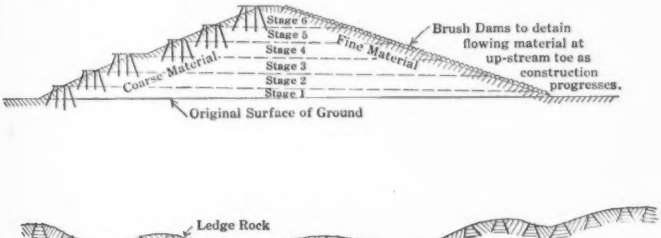

FIG. 28.—METHOD OF CONSTRUCTING EARTH DAM BY SLUICING WITHOUT THE USE OF A CENTRAL POOL.

A modification of this method would be its use in connection with a dam constructed by the semi-hydraulic-fill process. In this method, trains of dump cars are run out on the trestles and dumped. After the cars are dumped, small giants are turned on the dump under the trestle and the material is sluiced away in an up-stream direction, the heavier rocks remaining in the position in which they are dumped from the cars. The remainder of the method is the same as that already outlined.

By excluding the finest particles from the dam, a structure is obtained which, although not theoretically as impervious as if these excessively fine particles were included in the fill, is, nevertheless, practically water-tight. It is claimed for this method that it places the finer material near the up-stream face where it will do the most good, and produces a much more stable structure than one with a puddled core at the center. The down-stream portion of the structure, containing the coarser particles, will act, to a certain extent, as a drain for the

Mr. Justin.

more impervious up-stream portion of the dam, and the line of saturation will enter the foundation at a point much farther up stream than would be the case if the usual central pool were used.

By wasting the finest particles a considerable yardage would be sacrificed, but as their inclusion in the structure has been shown to be a source of danger, it is surely the part of true economy to omit them. Also, these rejected fines are not entirely wasted. Flowing up stream from the dam, they will be deposited and tend to fill the interstices of the natural ground surface and thus decrease the flow of water through the soil under the dam.

There are doubtless certain materials, the effective sizes of which are so small that this method would not be applicable but, in that case, it is the part of wisdom to use some method other than hydraulic sluicing for construction.

Mr. Hazen.

ALLEN HAZEN,* M. AM. SOC. C. E. (by letter).—The writer is gratified to have had nineteen engineers, representing the widest experience in dam construction, take part in the discussion of his paper. The interest thus shown is evidence of the importance of the questions raised, and the writer feels that this broad and representative discussion will do much to clear them up. As these discussions, for the most part, consist of additional data and new points of view not inconsistent with the propositions which the writer has presented, he will not attempt to review them in detail, but will refer only to a few matters.

Some of the discussions show a misconception of the conditions at the Calaveras Dam prior to the slip. Without attempting a complete statement, it may be said that no puddle-core material found an outlet through the dry fill to either face of the Calaveras Dam at any time. The material in the up-stream toe which slipped was placed in horizontal layers only, and not on slopes. The lower toe, which was thinner and which did not slip, was placed in part by dumping on slopes. Hence, so far as the placing of material in this manner tended to weaken the embankment, it would have weakened the lower toe; and as this toe did not fail, certainly the manner of placing played no part in the actual slip.

At the time of the slip the concrete paving on the upper slope of the dam extended only to Elevation 663, while the top of the dam was at Elevation 770. The concrete paving was, therefore, 107 ft. below the top of the embankment and can have had very little influence on the conditions that led to the slip.

The water surface in the lake at the time of the slip was 116 ft. below the top of the dam, and the difference in elevation between the pool in the center of the dam and the lake was certainly sufficient, so that no retardation of drainage can be assumed to have resulted from back pressure.

* New York City.

Mr. Hazen.

It must be remembered also that water had been stored for three seasons before the slip, and that a year previous thereto it had been 20 ft. higher than it was at the time of the slip.

In regard to cost, it may be interesting to note that the company's records show that the actual direct cost of sluicing about 1 500 000 cu. yd. of material to the dam was 26.8 cents per cu. yd. When the costs of camps, roads, engineering, interest during construction, and all other expenses are included, the total cost was 34.6 cents per cu. yd. This, of course, gives no indication of what prices would be in 1920, but the writer believes that neither at that time, nor at the present time, could dry fill be placed at a price comparable with that at which the material was sluiced.

Mr. Holmes' description of the dams for which he has acted as Resident Engineer, with the analyses of materials and tests of permeability, are of the greatest interest. The core has been handled so that the grain size in some cases, on the analyses submitted, is considerably above the limit suggested by the writer; and not only this, but the record of Mr. Holmes' tests on permeability which he has given the writer in greater detail than in the discussion, show that the rate of seepage and the actual leakage through this coarse core material are not greater than those computed by the method used by the writer, but, instead, are somewhat smaller. In other words, there is complete demonstration that core material of this relatively coarse grain size is, for practical purposes, sufficiently water-tight.

Messrs. Burr, Henny, and Binckley refer to the fact that the dividing line between the core and the toe is not vertical, but on an incline, and that there is an upward component of the pressures of the core on the toe, which tends to lift the toe and reduce its resistance to sliding. This matter is more important as the core is wider. It was important at Calaveras. It would not be important for a much narrower core. Mr. Henny contributes an interesting calculation on the reduction in stability growing out of the presence of water back of the dam at various elevations.

Mr. Dunham also suggests that the Calaveras Dam probably slipped on an inclined surface rather than a horizontal one, and the writer believes this surmise is correct. Near the center line of the dam it was clear that the line of slippage was approximately 60 ft. above the bottom of the valley. At the base of the upper toe all the materials slipped (including the gravel from the creek bed that had been placed hydraulically), extending clear down to the natural surface and perhaps below it. These two points are known definitely, otherwise the slipping surface cannot be located, and numerous borings made after the dam slipped did not afford a basis for locating it. The material found in the borings was just the same whether it had slipped or not, and although the borings were made with a view to determining the position

Mr. Hazen.

of the surface of slip, the most careful attention failed to show any indications of it. The surface on which the Calaveras slip occurred, therefore, remains, and must remain, except for the two points mentioned, a matter of conjecture. Mr. Dunham is right, however, in saying that it was not horizontal.

All these matters are of importance in considering the stability of dams. How adequately to take them into account in future plans is the problem that is presented.

Reference has been made to the tests of frictional resistance of the materials at San Pablo. The writer hoped that G. W. Hawley, M. Am. Soc. C. E., Resident Engineer of the San Pablo Dam, who built the apparatus and made the tests, would present a description of them and a statement of the results obtained. As he has not done this, the record of a few results of the first tests made by Mr. Hawley, taken from the writer's notebook, is given in Table 7.

Approximate average for results with pressures corresponding to more than 100-ft. depth of fill.....		0.45	0.49	0.54

Each figure in Table 7 represents the mean between two observed values. The first was of the pressure required to start the movement; that is, the maximum pressure observed before there was a slip; and the second was the pressure required to keep the slip moving after it was once started. In a general way, the latter pressure was about 10% less than the former. In other words, the friction required to start movement was 5% greater than that indicated by the figures, while the friction after movement was 5% less.

The writer believes that this kind of experimentation offers promise of better knowledge of different materials, and of the effect of varying

quantities of water in the same material; and he hopes that a complete record of the San Pablo tests may be published, and tests of other materials made. Mr. Hazen.

Answering Mr. Dunham's questions, the section of the dam for which he asks may be found in *Engineering News-Record*, of December 26th, 1918, and a summary of the data relating to the slip may be found there and also in the issue of April 4th, 1918.

Mr. Morgan thinks that a clear distinction should be made between the compacting of the material by drainage and that by consolidation through settling under water. It seems to the writer that such a distinction may be hardly practicable, and he is inclined to include the settling through water (which necessarily involves an upward flow of the water through the material) under the term drainage.

The little volcanoes at the top of soft core material, which Mr. Morgan has mentioned, have been observed by the writer, who believes that they probably occur only in material with a large percentage of voids, and that they do contribute largely to the rapid first consolidation of material. Later, the material becomes more solid, and this volcano action stops. It must stop before the material has acquired any useful degree of stability, and for this reason the volcano action cannot be an element of importance in the final consolidation. It may be that it accounts for the original consolidation of the material to approximately 50% of voids in the course of a few months, which would otherwise be difficult to explain.

There can be no doubt that drainage of saturated material is essential to consolidation. The core material is deposited under water. Its voids are completely filled with water. Consolidation can take place only as the surplus water is excluded.

The conditions of flow are essentially the same whether the movement of the water is vertical or horizontal. It may be that the hydraulic slope for the vertical flow will be greater than was mentioned in the paper. This proposed value did refer to horizontal flow. For vertical flow the hydraulic slope may be taken as the specific gravity of the material less 1.00. A material with 50% of voids has a specific gravity wet of 1.825, and the hydraulic slope for upward flow is therefore 0.825. Using an estimated rate of seepage based on this value would change the figure, but not the essential conditions as described.

How to get the excess water out of the core material is the one dominant problem with fine-grained core material. It is the water that holds the particles apart and prevents consolidation; if it can be taken out by drainage, consolidation follows as a matter of course and to the full extent that water is removed.

In considering experience with shallower materials elsewhere, evaporation from the surface and bringing water up from below by capillarity is often a dominant factor, and this must be kept in mind in making comparisons with observations obtained under such conditions.

Mr. Hazen.

Mr. Paul thinks that the writer's descriptions of 50% material are inconsistent in that at one time it is described as being capable of standing up in a boring driven beyond the casing for several feet, and in another paragraph as exerting full lateral pressure. The explanation of the apparent discrepancy lies in the cohesion of the material. Cohesion is real and important. It is cohesion that holds the vertical sides of a cut in such material to a depth of several feet. It is cohesion that gives it the firmness of stiff putty. It is cohesion that holds the particles together as an arch about the borings below the end of the casing. Cohesion exists equally in a great mass of material under heavy pressure, but there it becomes so small in comparison with the pressure, that it is no longer able to maintain stability and the material becomes capable of flowing.

The depths of penetration mentioned by Mr. Paul, as observed at Calaveras, are understood by the writer to be maximum depths at special points at a time long before the slip. Before the slip occurred there had been a temporary cessation of operations, and the core material had consolidated and hardened to a point where penetration was resisted at a depth of a very few feet; and so far as this kind of evidence goes, the core material at the Calaveras Dam at the time of the slip was satisfactory.

The one great lesson to be learned from the Calaveras slip is that material consolidated to this extent and having the consistency of stiff putty, capable of resisting penetration is, nevertheless, capable of flowing in large masses.

Another question in which the same line of thought is involved is whether deductions from readings of small and very ingenious pressure gauges may be safely used in calculations of pressure in large masses. The writer is in doubt on this question, and is disposed to proceed slowly pending further demonstration. The question which he raises is not as to the accuracy of the record of the gauges (of which he has no knowledge), but whether, in view of cohesion, actual pressures on very small areas really indicate conditions in large masses. For instance, would the pressure gauge against the surface of material standing beyond the casing of a bore hole show full lateral pressure? The writer is in no doubt of the fact that some material that will stand in that way without support is, nevertheless, capable of flowing almost like water when the mass is sufficiently great. Mr. Goldbeck's gauges seem to be ingenious devices, and the results obtained by their use in actual dams will be studied with interest.

Mr. Muckleston's observations suggest the possibility of chemical treatment to improve the physical condition of colloidal clay. This certainly opens interesting possibilities.

Mr. O'Shaughnessy suggests reducing the flow line of the Calaveras Reservoir 37 ft., in the interest of greater safety. Reducing the flow line by this amount would reduce the capacity of the reservoir by about

19 300 000 000 gal., or by about 40 per cent. The full proposed capacity is not too much to hold the waters of floods that occur only at intervals of several years, and make them available at all times, especially during the dry years sometimes experienced in California. If the flow line should be lowered as proposed, it would reduce the maintainable supply through a series of years by 10 000 000 gal. per day. In the San Francisco District, 10 000 000 gal. of water per day are worth a certain number of millions of dollars. To reduce the height of the dam, and with it the capacity and value of the source, should not be done unless there is valid reason for believing that a dam built to the full height cannot be made safe. Mr. Hazen.

Mr. Binckley's statement in regard to Mr. Schuyler's later views and experience, unfortunately not expressed in writing before Mr. Schuyler's death, are most interesting and helpful; and it is gratifying to the writer that the views which he has presented are supported in this manner.

Paper No. 1459

NOTES ON TUNNEL LINING FOR SOFT GROUND*

By S. Johannesson and B. H. M. Hewett, Members, Am. Soc. C. E.

With Discussion by Messrs. J. C. Meem, E. G. Haines, Philip Aylett, Walter C. Parmley, C. M. Holland, T. Kennard Thomson, Orrin L. Brodie, and S. Johannesson and B. H. M. Hewett.

Synopsis.

In the construction of tunnels, particularly under compressed air in soft soil, the engineer has met a number of difficulties connected with the lining, often obscure in their origin, which for that reason have caused anxiety, delay, and unforeseen expense.

In this paper the more important of these difficulties are stated and methods of avoiding them suggested. These suggestions are discussed both from a practical and theoretical point of view. It is the purpose first to attempt to determine the causes for the distortions and displacements common to tunnel linings, and, second, to suggest how they may be avoided by the modification of existing practice. The subject, however, is so extensive that, in order to keep the paper within reasonable limits, a general outline only will be presented.

For the sake of convenience, the paper is divided into sections as follows:

1.—Behavior of tunnel lining during construction.
2.—Determination of stresses in tunnel linings.
3.—Conditions for stable equilibrium.
4.—Stresses in tunnel lining during construction.

* Presented at the meeting of April 21st, 1920.

5.—North River silt.
6.—Ruling requirements for the erection and design of tunnel lining.
7.—Design of tunnel lining.
8.—Materials of construction.
9.—Secondary lining.
10.—Cost of tunnel linings.
11.—Conclusions.

1.—Behavior of Tunnel Lining During Construction.

A common experience when building a shield-driven cast-iron lined tunnel is that, although it may be possible to erect the lining true to line, level, and shape, it is difficult and even impossible to keep it so during the construction period.

Immediately after the shield has left a newly erected ring of the lining the ring may move up or down and as likely as not it will change its shape, sometimes in one direction and sometimes in another. If the deformation threatens to become excessive, the tunnel has to be braced. Afterward it may be found that this bracing, although carefully placed, becomes loose and ineffective because the lining has started to deform in another direction. Then the bolts may have to be retightened and the water-proofing of the joints and the bolt holes may have to be done again every time the lining changes its shape.

The up or down movements may be even more serious. In the Pennsylvania Railroad Tunnels under the North River at New York City at one time the tunnel started to rise suddenly immediately behind the shield for some at that time unexplained reason, and rose as much as 12 in. above the level at which it was erected. This naturally caused much concern. The work was closed down for about one month and the tunnel lining redesigned.

In another tunnel under the East River at New York City, the lining settled at one place to such an extent that there was not sufficient clearance left for the traffic to pass through, and thus necessitated the reconstruction of this part of the tunnel.

It is evident that to take care of these distortions and displacements is expensive both in money and time and adds greatly to the cost of the finished structure. Therefore they should, if possible, be avoided.

2.—Determination of Stresses in Tunnel Linings.

The primary function of the lining of a tunnel is to support the surrounding soil. In addition, it is often necessary and nearly always desirable that the lining should be capable of preventing the infiltration of water which may be present in the ground under a consirable head. Furthermore, when the tunnel is constructed by the shield method the lining must be able to support the thrust of the shield rams.

The lining of a tunnel is subject to stresses caused by the external forces, and only when these are known is it possible to determine the stresses in the lining.

Assuming material with small angle of repose, the vertical forces on the upper half of the tunnel are the weight of the soil, the weight of the lining, and the possible live loads above the tunnel within two vertical planes tangent to the sides of the tunnel. The force on any given area of the tunnel is that portion of the forces which is vertically above the area.

The vertical forces on the lower half of the tunnel are equal to the vertical forces on the upper half of the lining, plus the weight of the tunnel and its contents. The distribution of these forces is uncertain, but can generally be assumed with sufficient accuracy. The horizontal forces, which must be balanced on the two sides of the tunnel, as the tunnel otherwise will be in sidewise motion, can be determined by means of Rankine's "Theory of Conjugate Stresses."

Let p = the vertical load on a unit of horizontal surface within the ground;

p_1 = the horizontal soil pressure on a unit of vertical surface at the same depth; and

α = the angle of repose of the soil.

Then, in accordance with Rankine's theory,

$$p_1 = p \frac{1 - \text{sin. } \alpha}{1 + \text{sin. } \alpha} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (1)$$

This formula represents the active horizontal pressure of the soil. The soil is, however, able to resist a greater horizontal force, represented by

$$p_2 = p \frac{1 + \text{sin. } \alpha}{1 - \text{sin. } \alpha} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (2)$$

This force, p_2, is called the passive pressure of the soil.

The horizontal pressure on the tunnel is always at least equal to the active pressure, p_1, but if the condition of the internal stresses in the tunnel lining should so require, a greater horizontal pressure will be developed of such a magnitude as will be required to provide the necessary equilibrium, but under no circumstances greater than p_2.

In order to find the stresses in the tunnel lining it is necessary to determine which value of the horizontal force, between the limits of p_1 and p_2, is in action. This can be determined by the fact that such a horizontal force is in action as will produce the least internal work.

The least internal work will be produced if the stress polygon coincides with the neutral axis of the tunnel lining. To find if this coincidence is possible, it is necessary, first, to determine whether a horizontal force which would produce the coincidence might be applied, and, second, whether such a horizontal force would come within the limits of the active and passive forces. If it does, the stress polygon will coincide with the neutral axis, and the tunnel lining will be in direct compression only.

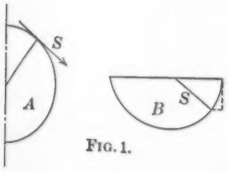

FIG. 1.

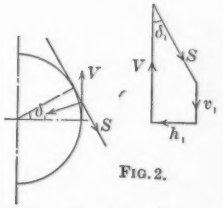

FIG. 2.

In Fig. 1, A represents half the circumference of a tunnel, and B a force diagram for the tunnel. It will be seen that, if the direction of the force S is parallel to the tangent to the corresponding point of the circumference, the stress polygon will follow the neutral axis; it will be seen, also, that for any given vertical force there is always a horizontal force which will produce the desired results. The value of this horizontal force can be determined as follows:

The forces acting on the portion of the lining between the horizontal radius and a radius forming an angle δ_1 with the horizontal are the tangential stress, S, in the lining, the vertical stress, V, and the external forces with a vertical component v_1 and a horizontal component h_1.

Fig. 2 shows that

$$h_1 = (V - v_1) \tan. \delta_1 \ldots\ldots\ldots\ldots\ldots\ldots (3)$$

where V is the vertical load on one-half of the tunnel, and v_1 is the vertical load on the portion of the lining considered.

The horizontal force on a portion of the lining between two radii forming angles of δ_1 and δ_2, respectively, with the horizontal is

$$h_1 - h_2 = (V - v_1) \tan. \delta_1 - (V - v_2) \tan. \delta_2 \ldots\ldots\ldots\ldots (4)$$

In a circular tunnel with a radius, r, the horizontal pressure per unit of area is

$$p_i = \frac{h_1 - h_2}{r \, (\sin. \delta_2 - \sin. \delta_1)}$$

or

$$p_i = \frac{(V - v_1) \tan. \delta_1 - (V - v_2) \tan. \delta_2}{r \, (\sin. \delta_2 - \sin. \delta_1)} \ldots\ldots\ldots (5)$$

This pressure, p_i, is, in the following, termed the ideal pressure.

In a more convenient form for use, p_i may be expressed by the following equation, which gives an approximate value only and in which w represents the unit weight of the soil, and δ the radial angle:

$$p_i = p_1 + 0.11 \, (2 + \sin. \delta) \, (1 - 2 \sin. \delta) \, w \, r \ldots\ldots\ldots (6)$$

If $p_1 < p_i < p_2$, the tunnel lining will be subject to direct compression stresses only.

Assuming that the vertical forces on the lower half of the tunnel are distributed in the same way as they are on the upper half, which is near enough for the present purpose, in order to obtain the condition that the lining may be in direct compression only the active horizontal pressure at the bottom of the tunnel should be no larger than the ideal pressure, p_i, at the top of the tunnel.

In order to determine what angles of repose would produce such pressures under certain given conditions, the pressures, p_i, have been determined for circular tunnels with diameters of 12, 18, 24, 30 and 36 ft., respectively, and with the assumption that the vertical pressure at the top of the tunnel is 4 000 lb. per sq. ft. and that the weight of the material is 120 lb. per cu. ft. The results are plotted on Fig. 3, and by applying Equation (1) it is found that, under the assumptions made, direct compressive stresses only will occur when the angle of repose is not less than the values given in the following table:

Diameter of tunnel, in feet.	12	18	24	30	36

Vertical Downward Pressures
Passive Horizontal Pressures
Vertical, Horizontal and Ideal Horizontal Earth Pressures, In Pounds per Square Foot

FIG. 3.

If the vertical pressure at the top of the tunnel is less, the angles will be greater, and if the weight per cubic foot of the material is less, the angles will be less; but generally it may be said, that in order to obtain direct compressive stresses only in the lining of a circular tunnel, the diameter of the tunnel must be limited to a certain value which varies directly as the value of the angle of repose. This limiting value of the diameter is about 12 ft. when the angle of repose is 10°, and about 43 ft. when the angle of repose is 30 degrees.

If the angle of repose of the soil is less than as determined above, the lining will be subject to bending stresses in addition to the direct compression stresses. These bending stresses may be determined by means of a stress diagram. It is evident that the horizontal forces to apply are the active horizontal pressures, when they are larger than the ideal pressures.

In Equation (5) the term, r (sin. δ_2 — sin. δ_1), represents the vertical projection of the area of the tunnel lining upon which the horizontal pressure is acting. If this area is reduced without similarly reducing the horizontal projection of the area, the value of p_t will increase. Such a reduction can be accomplished by making the tunnel elliptical, with the major axis horizontal. The ratio between the horizontal and vertical diameters of the ellipse can be found as follows:

First, determine the maximum passive horizontal pressure per unit of area at the top of the tunnel, and the active horizontal pressure per unit of area at the bottom. If the latter is equal to the former, an elliptical tunnel may be constructed which will be subject to compressive stresses only, and the ratio between the horizontal and vertical diameters of the ellipse will be equal to the square root of the ratio between the active pressure at the bottom of the tunnel and the ideal pressure at the top of the tunnel.

If the maximum passive horizontal pressure at the top of the tunnel is less than the active horizontal pressure at the bottom of the tunnel the lining will be subject to bending stresses which, however, will be as small as possible if the ratio between the horizontal and vertical diameters of the ellipse is equal to the square root of the ratio between the maximum passive pressure at the top of the tunnel and the corresponding ideal pressure.

If the maximum passive horizontal pressure at the top of the tunnel is greater than the active horizontal pressure at the bottom of the tun-

nel, elliptical tunnels subject to direct compressive stresses only may be designed, with the ratio between the horizontal and vertical diameters varying between the square root of the ratio which the active bottom horizontal pressure bears to the top ideal pressure and the square root of the ratio which the maximum passive top pressure bears to the top ideal pressure.

The ratio between the vertical and the horizontal diameter in soil with an angle of repose of 2° 52′, weighing 120 lb. per cu. ft. and when the pressure at the top of the tunnel is 4 000 lb., is approximately as 9 to 10.

It may be stated, therefore, that in soil with an angle of repose producing bending stresses in a circular tunnel, it is possible to reduce and sometimes to eliminate the bending stress by making the shape of the tunnel elliptical.

3.—Conditions for Stable Equilibrium.

If the angle of repose is small, the distribution of the vertical forces on the lower half of the tunnel may be different from that assumed, because the active vertical forces become effective. In that case the distribution may be assumed to be as follows: Determine the upward forces which, in accordance with Rankine's theory are, per unit of area:

$$p_3 = p\left(\frac{1 - \sin.\ \alpha}{1 + \sin.\ \alpha}\right)^2 \quad \ldots\ldots\ldots\ldots\ldots\ldots (7)$$

and distribute the difference between the upward and downward forces, including the weight of the tunnel, uniformly over the horizontal diameter.

If this difference is less than the weight of the tunnel, passive upward vertical forces are developed, and according to Rankine the maximum value of these is:

$$p_4 = p\left(\frac{1 + \sin.\ \alpha}{1 - \sin.\ \alpha}\right)^2 \quad \ldots\ldots\ldots\ldots\ldots\ldots (8)$$

It may be said, therefore, that if the total vertical downward forces are less than or equal to the total maximum passive upward forces as determined by Equation (8), the tunnel will not sink.

If the total active upward forces as determined by Equation (7) are greater than the total downward forces, it does not necessarily follow that the tunnel will rise, because the resistance to upward motion is greater than the total downward load; for, in addition to overcoming

the resistance of the load, the frictional resistance on two vertical planes from the top of the soil to the bottom of the tunnel has to be overcome.

Let D = the distance from the top of the soil to the bottom of the tunnel;

q_1 = the unit horizontal pressure at the top of soil; and

q_2 = the unit horizontal pressure at the bottom of the tunnel.

Then the frictional resistance will be

$$F = (q_1 + q_2)\ D \tan. \alpha \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (9)$$

It follows, therefore, that if the sum of the total downward load and the frictional resistance is greater than the total active upward force, the tunnel will not rise.

4.—Stresses in Tunnel Lining During Construction.

During the period of construction, the lining is subject to external forces and to conditions different from those which exist when this period of disturbance is past. In order to secure the safety of the tunnel during this period and to carry out the work of construction economically, it is necessary to determine in advance the stresses to which the lining may be subjected during the construction. This is particularly true when the tunnel is driven by the shield method through water-bearing ground.

Since the tunnel lining is used as the abutment for the shield rams, the stresses in the lining are influenced by the pressures exerted on it by the rams. These ram stresses consist of direct compression parallel to the axis of the tunnel, when the line of pressure coincides with the neutral axis of the skin of the lining. If not, additional weight of lining material is needed to take up stresses which are wholly temporary and constructional and which do not exist after the driving period is over. It is ordinarily present, however, with the usual type of cast-iron lining, and has been known to cause breakage of the lining and damage to the rams, particularly in tunnels of large diameter.

The conditions under which the shield is driven forward vary with the character of the ground. If the soil is firm it is excavated ahead of the shield, and the duty of the shield rams is mainly to overcome the frictional resistance. When the ground is soft and has a small angle of repose the shield may be used to displace part or all of the soil to be

removed to make room for the tunnel. In this case not only frictional resistance, but also the resistance to displacement has to be overcome.

When the shield is driven forward, displacing the soil, and particularly when this is done with the doors closed, the active horizontal pressures directly in front of the shield are increased to the value of the passive pressures, and at the same time rupture of the body of the soil occurs. In North River silt this increase is about 20 per cent. A proportional increase of the active upward forces will necessarily occur. If the existing condition of stable equilibrium is such that the total downward load and the frictional resistance about balance the upward forces, such an increase of the upward forces may cause the shield to have a strong tendency to "climb", and the tunnel to rise immediately after the shield has left the lining. This tendency to rise will extend only some distance behind the shield and will disappear when the abnormal active ground pressures have had time to readjust themselves. It may be relieved by admitting sufficient quantities of soil through the shield doors.

At the moment the tail of the shield leaves the lining, when the shield is pushed ahead, there exists an empty annular space around the lining. In firm soil it is probable that the first result will be that the lining will drop down to rest on the ground surface at the bottom and that the soil above the tunnel will close down until it bears against the upper half of the tunnel. Later, probably, the ground will close in at the sides. It is evident that the effect will be to introduce a bending stress in the lining, so that if the lining is not able to carry such stress the top of the tunnel will be pushed down and the sides will spread out until they bear against the soil. This tendency to distortion may be decreased, however, by filling the space with grout or other solid material.

In ground with a small angle of repose it is possible that, on account of its greater mobility, the soil may close around the tunnel immediately after the shield is pushed ahead. The construction conditions, however, will have appreciable influence on the stresses in the lining.

To begin with, the pressure of the compressed air produces bending stresses in the lining.

To illustrate this stress, diagrams have been made to show the varying conditions of stress produced by varying conditions of air pressure. Fig. 4 shows a force polygon and stress polygon under certain given conditions when the tunnel is under normal air pressure. Fig. 5 shows

the force polygon and stress polygon for the same tunnel under an air pressure of 25 lb. and Fig. 6 a force polygon and stress polygon when the air pressure balances the external pressure at the crown of the tunnel.

A comparison of these diagrams shows that while the internal stresses in the lining decrease as the air pressure increases, the eccentricity of the stress increases with increased air pressure. In cast-iron lining of the usual type, the bending moment introduced by the air

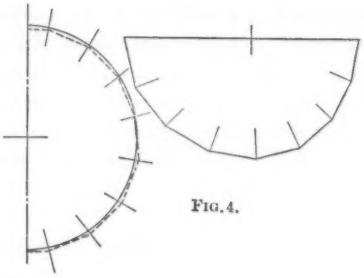

FIG. 4.

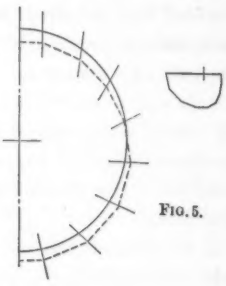

FIG. 5.

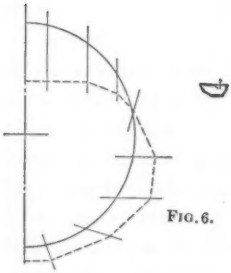

FIG. 6.

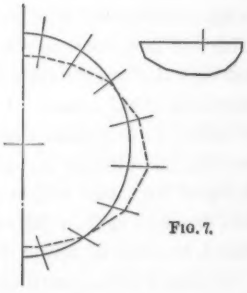

FIG. 7.

pressure may cause a tensile stress of several thousand pounds per square inch. As the cast-iron lining is not a continuous elastic structure, the effect of these bending stresses will be to open the joints between the segments. An inspection of the diagrams will show that the tendency will be to open the joints at the bottom of the tunnel on the inside and at the top of the tunnel on the outside. However, as the soil at the top may resist the tendency of upward displacement the probable net result will be a shortening of the vertical and a corresponding lengthening of the horizontal diameter.

As already stated, the pushing of the shield ahead without taking in the displaced soil increases the earth pressures in the vicinity of the shield. Similar results may be caused by pushing forward the shield in an adjacent tunnel, if that tunnel is sufficiently close. Fig. 7 shows the stress curve under these conditions. The tendency to distortion in this case is to increase the vertical and to decrease the horizontal diameter.

Stating them in the proper order, the tendencies to distortion (and if the lining is not able to withstand the stress, the actual distortions) will be, in soil with a small angle of repose, as follows: First, immediately after leaving the shield, the lining will rise, if the conditions are present, and at the same time increase the length of its vertical diameter and decrease that of the horizontal diameter. Soon after, when the soil conditions have become normal, the tendency will be to push in the lower half of the lining, thereby shortening the vertical diameter and lengthening the horizontal diameter. This tendency becomes more aggravated with an increase of air pressure. Finally, when the air pressure is removed, the tendency to distortion disappears, to a great extent, but at the same time the magnitude of the direct stress is increased.

The conclusions here arrived at correspond closely to the actual behavior of the tunnels driven through North River silt. The excessive rise of the Pennsylvania North River Tunnel previously mentioned, which caused the work to be stopped for a time, happened when both the tunnels were being driven close to one another and with the doors closed. The rise was effectively checked by driving one shield well in advance of the other and by taking a sufficiently large quantity of the displaced soil into the tunnel through the shield doors; in fact, it was found that the path of the shield could be adjusted readily by gauging the volume of the soil taken into the tunnel. The volume naturally depends upon a number of conditions, including the diameter of the tunnel; if that is small enough, it may be possible to push the shield ahead with the doors closed without producing a rise of the tunnel; in fact, this was frequently the experience in the tunnels of the Hudson and Manhattan Railroad under the North River which, in addition, were so far apart that the adjacent shields had little or no effect upon each other.

The flattening tendency indicated by the theoretical determination of stresses under air pressure, was a common experience in all tunnels

driven through the North River silt. In all cases, the ring of the lining was originally built true to shape. If after erection it began immediately to increase its vertical diameter, this change of shape stopped within about two weeks; thereafter the lining commenced to increase its horizontal diameter and continued to do so until the secondary lining was placed. If no initial shortening of the horizontal diameter occurred, the lining began, soon after erection, to flatten and this often continued until checked by internal bracing.

The conclusions to be drawn from these conditions are that, for safety and economy, it may be advisable to design the lining so as to be able to carry not only the permanent stresses, but also the construction stresses, which include bending, even though the permanent forces produce compressive stresses only, and that consequently the primary lining should be the entire carrying member.

5.—North River Silt.

In the foregoing discussion, references have been made to soils with a small angle of repose, and it may be pertinent, therefore, to state some of the characteristics of the North River silt underlying the North River and adjacent waters, which is an example of a soil with a small angle of repose.

During the period of construction of the tunnels under the North River for the Pennsylvania Railroad and the Hudson and Manhattan Railroad, a great number of tests, experiments, and analyses were made to determine the characteristics of the silt. As a number of tunnels already have been built in this material and more will be built, the most important results obtained will be stated here.

The weight of the silt increases with the depth below the river bed, at least to the depth that tests were made, which was to the bottom of the tunnels. At a depth of 15 ft. below the river bed, the silt weighs about 104 lb. per cu. ft.; at a depth of 38 ft. it weighs about 110 lb. and the average weight of the silt surrounding the tunnels is 108 lb. per cu. ft. The silt surrounding the tunnels contains 55% of water by volume.

The unit weight of the silt and its water content vary with the tide. At high tide the weight is greater than at low tide and the water content is less. This points to the probability that the solid particles of the silt come closer together at high than at low tide, and this is also evidenced by the fact that there is a reversing tidal motion of the silt, which rises as the tide falls and falls as the tide rises. This tidal rise and fall

amounts to an average of about ⅛ in. at the level of the tunnels. It is to be presumed that it varies from zero at the bottom of the silt to a maximum at the top.

A body embedded in the silt will move up and down with the silt, but if it is in stable equilibrium, it will not move in relation to the silt.

The angle of repose of the silt surrounding the tunnels was determined to be less than 3 degrees. This was done by analyzing many hundreds of observations of the external pressures on the tunnel lining, obtained by means of specially constructed and highly sensitive pressure gauges inserted in holes in the skin of the cast-iron lining.

The fact that a shield with its doors completely closed can be forced bodily through the silt without taking a shovelful of muck into the tunnel and without requiring undue jack pressures to be developed shows that this particular soil is essentially a viscous fluid. Such a thing could not be done in clay or sand or in a mixture of such. Observations on the jack pressures used to start an actual shield in movement through the silt confirm, when analyzed, the fact that the material has an angle of repose of less than 3 degrees.

Another striking indication of the quasi-fluid nature of the silt is afforded by its vertical fluctuation due to the tidal rise and fall of the water in the North River above it. The ordinary range of tide here is only 4 or 4½ ft. and yet, at the elevation at which the tunnels lie, this small tidal range produces a change of elevation in the silt of about ⅛ in. Under a tidal range of 10 ft., a change of ¼ in. in the elevation of the silt, or rather in that of the tunnel embedded in the silt, has been observed.

Certain other characteristics of the silt, observed during the construction of tunnels through this soil, should also be noted. When subjected to air pressure, the silt has the nature of a stiff clay and its consistency may readily be varied by changing the air pressure, that is to say, when the air pressure nearly balances the soil pressure, the material becomes quite stiff, but as the air pressure is reduced the silt becomes softer and softer.

6.—Ruling Requirements for the Erection and Design of Tunnel Lining.

It is evident from the previous discussion that, if the tunnel lining is designed in such a manner that it is able to carry the stresses to which it may be subjected, both during the period of construction and there-

after, and if the work of construction is carried out properly and with due regard to the peculiarities of the soil through which the tunnel is driven, the usual difficulties and expense experienced in keeping the tunnel true to line, grade, and shape will be avoided.

The remedies for the rising or sinking of the tunnel are apparent, providing the tunnel is in stable equilibrium, and this is naturally a primary necessity. When the tunnel rises, it is probably due to the existence of excessive external pressures caused either by an adjacent tunnel shield or by the displacement of the soil by the shield of the tunnel itself.

The prevention of rising is to make such an adjustment of the quantity of material brought in through the shield doors that these excessive external pressures are not brought into existence. When the tunnel sinks it is plainly due to leakage of water and soil through the joints of the lining over the lower portion of the periphery. The prevention consists in making the lining water and mud tight at the time of its initial erection, or as soon after as possible.

The prevention of deformation lies entirely in the design. If the lining is designed so that it is able to carry the stresses that may be brought upon it, both during and after the construction period, no deformation will occur. It is of importance, therefore, that the lining should be designed with due regard to this requirement.

When the art of building cast-iron lined subaqueous tunnels was in its infancy the size of the tunnels was kept within small limits and the tunnels were built through ground that was favorable for safe construction.

As time went on, and there developed the necessity for tunnels of larger size and in fixed locations regardless of the suitability of the soil and depth of waterway encountered, fresh problems were presented to the tunnel engineer, which indicated that either the design or the material of the lining, or both, had outgrown their original usefulness from the standpoint of safety as well as of economy. In what follows, therefore, the design of tunnel linings will be discussed while keeping in mind the safety and the economy of the design under varying conditions, both of size and surrounding material.

7.—Design of Tunnel Lining.

In undertaking the design of a tunnel lining for any given purpose and under any given conditions, the following points have to be kept

in mind: The shape, the strength, the material of construction, the water-proofing, the time required for construction, and the cost of maintenance and operation.

As regards the shape, if the cross-section of the tunnel is such that the lining is subject to direct compressive stresses only or, if that is not obtainable, to the least possible bending stresses, the least quantity of construction material will be required per unit length of the periphery. As stated in the section on determination of stresses, this points to the use of an elliptical cross-section, at least when the angle of repose of the soil is small. When it is possible to arrange the internal clearance profile in an elliptical cross-section so that no space is wasted, a further economy is obtained by having decreased the vertical diameter, because both the stresses in the lining and the difficulties of construction are thereby decreased. The possibilities of making the shape elliptical have to be studied in each specific case, and therefore no detailed comparisons, as regard economy, between circular and elliptical tunnels can be attempted in this paper.

In most cases it is necessary or advisable to maintain the proper lines and grades, either to permit the passage of the traffic for which the tunnel is intended or for the sake of appearance. Therefore, some additional clearance, say, from 3 to 6 in. all around the inner periphery, should be provided for the adjustment of the unavoidable deviations from the proper lines and grades that will occur during the driving of the tunnel.

As regards the strength of the lining, it has been shown that, under certain conditions, the lining is subject to bending stresses. For the purpose of avoiding non-elastic deformation, the lining should be able to carry such stresses. The ability of various lining materials to do this will be discussed in the following section. However, it may be repeated here that on account of the fact that the bending stresses occur during the construction period, as well as after, the lining placed at the time of construction should be strong enough to carry all stresses without any secondary lining placed at any later date.

The economy of construction depends not only on the unit cost of the material or materials of which the lining is constructed, but also on the quantity of material required. This includes not only the cost of procuring the materials, but also their cost of erection. It will be remembered that, if the tunnel is driven under air pressure, the cost of

labor under these conditions is exceptionally high, and that, therefore, such materials should be selected, and so arranged, as to require as little labor under compressed air as possible.

In this connection, it may be noted that while the internal diameter of the tunnel is determined by the use for which the tunnel is intended, the external diameter and consequently the quantity of excavation is in addition determined by the thickness of the lining. Therefore, in comparing various types of lining from the point of economy, the quantity of excavation should also be considered.

A further matter of economy is that of the period of time required to finish the tunnel ready for operation. Generally it is desired to complete the construction as soon as possible, because the tunnel is imperatively needed. The loss of money by reason of the tunnel not being ready for operation often cannot be estimated definitely but is, nevertheless, an important item. In addition, the monthly overhead expenses continue about the same during the whole period of construction, and the interest on the capital invested increases with the time of construction. This indicates as advisable an investigation of the relative periods of time needed to construct tunnels of various sizes, shapes, and materials.

A preliminary study of the rates of progress attained in the different New York river tunnels showed that, generally speaking, the larger the tunnel the less progress, measured in linear feet of tunnel driven per month, was attained under any given set of conditions.

When the weight of cast-iron lining corresponding to the linear feet of tunnel driven per month was computed, it was found that there was a fairly constant weight of cast-iron lining erected per month under any given set of ground conditions, irrespective of the size of the tunnel. This is shown in Table 1.

TABLE 1.—Weight of Cast-Iron Lining Erected per Month in Compressed Air Tunnels at New York City.

Material.	Weight of Cast-Iron Lining Erected per Month, in Tons.			
	P. R. R., North River.	H. & M. R. R., North River.	Dual Subway, East River.	Average.
Sand, gravel, etc.	660	.....	484	550
Mixed ground	300	300	182	250
Rock	235	220	243	230
Silt	1 650	1 800	1 665	1 750

The cast-iron lining of the tunnels built in the neighborhood of New York City weighs, in pounds per linear foot of tunnel, about twenty-two times the square of the outside diameter expressed in feet. Consequently, the fact that the weight of iron lining erected per month under any given conditions of ground is more or less constant, makes it possible to foretell the approximate monthly progress which a tunnel of any given diameter will make under any given conditions of ground. This estimate has been plotted to show the result in graphical form (Fig. 8), and it is interesting to see that the line of progress starts at zero for zero diameter, rises rapidly to a maximum for a tunnel of about 10 ft. in diameter, and then diminishes as the diameter of the tunnel is increased.

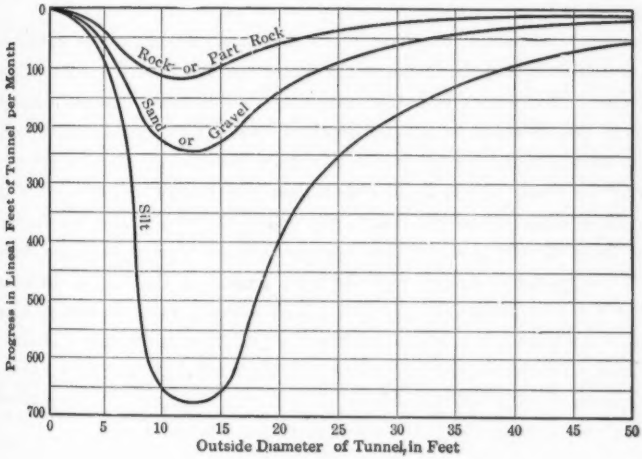

FIG. 8.

It may be said, therefore, that for shield-driven tunnels lined with cast iron of the usual type (and probably for shield-driven tunnels lined with any kind of material) the smaller the diameter, down to about 10 ft., the quicker progress will be made, the less the overhead and the interest charges during construction will be, and the sooner the tunnel will be ready for operation. This means that it is economically sound (provided that the purpose for which the tunnel is intended is not impaired thereby) to build a number of small tunnels instead of one large one. For example, it is thoroughly sound to provide a two-line railway tunnel by building two single-line tunnels rather than one

double-line tunnel, provided the quantity of material and work for the two single tunnels does not become so large in comparison with those items for the double-line tunnel that the advantage gained in the shorter construction period is counterbalanced.

The same reasoning applies to sewer tunnels, water supply tunnels and in fact to all cases where the traffic may be subdivided. A further incidental advantage is hereby gained, in that with a plurality of tunnels one or more may be shut down for repairs at times of slack traffic without shutting off the entire traffic. A constructional advantage gained by use of several small tunnels in place of one large one is that the difference in pressure between the top and bottom of the tunnel is less.

Most tunnels which have to be driven under navigable waters are limited as to the depth below the water surface at which they may be placed. For example, public authority may require that no encroachment may be made on a water depth of 40 ft. This fixes the elevation of the crown of the tunnel and this in turn fixes the position of the roadway or track which is placed within the tunnel. The smaller the vertical diameter of the tunnel the nearer to the surface this roadway or track may be kept and thus not only are the approaches made shorter or the gradients easier, and the total length of the tunnel decreased, but the vertical height through which every person or vehicle which uses the tunnel has first to be lowered and then to be raised is diminished. Thus a saving in energy is introduced and this saving is continuous throughout the entire life of the structure. If capitalized, this saving may amount to an appreciable sum of money.

8.—Materials of Construction.

Brickwork and Concrete.—Most of the usual materials of construction have been adopted for tunnel linings, and may be used if they suit the existing conditions. A tunnel driven through non-water-bearing rock may not need any lining at all, or perhaps only a facing of concrete to improve the appearance and to protect the rock against weathering. A tunnel constructed in dry soft soil may be lined with brick or concrete, providing that no shield-ram pressures have to be supported on the lining and that no soil pressures are likely to occur until the mortar or concrete has set. This indicates the use of brickwork or concrete,

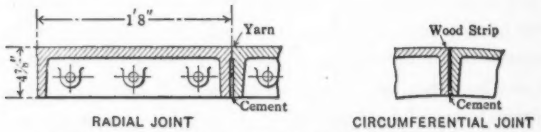
particularly as a secondary lining. The primary lining may be either a temporary timber construction or a permanent lining of timber, concrete blocks or metal. In the first case the masonry lining should be able to carry the full external loads; in the second case the masonry lining is used either to carry part of the stresses or to provide a smooth interior for the tunnel or to protect the primary lining. The use of precast concrete blocks placed without mortar will be discussed later.

Wood.—On account of its lack of durability, the use of wood is generally limited to temporary lining, but for this purpose it is quite common, from the timbering of a heading to the lining of full-size tunnels. For water-carrying tunnels in water-bearing soils, however, wood may be a suitable material. A special case where wood is indicated as a proper material for tunnel lining, is that of discharge tunnels of power houses, as it has been the experience that concrete or mortar disintegrates under the action of the discharge water. A wooden tunnel lining may be either arch shaped and made of short lengths of timber with circumferential butt joints, or it may be made rectangular, subjecting the timber to bending stresses. On account of the softness of this material, an internal wearing surface should be provided, either of masonry or of renewable planks.

Cast Iron.—Under proper conditions, cast iron is a material eminently suitable for use as tunnel lining on account of its rugged, durable character and its ability to carry compressive stresses.

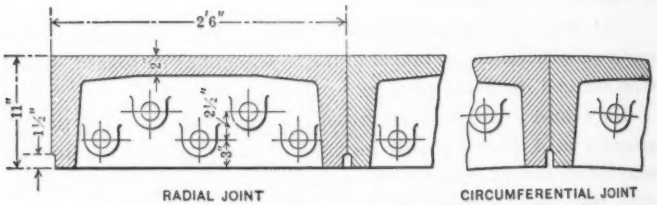
The tunnel shield, and incidentally the cast-iron lining of the type generally used, was originally invented by Marc Isambard Brunel and patented by him in 1818, but the segmental iron lining was not adopted until 1869 when it was used for the Tower footway tunnel, with an outside diameter of 7 ft. 1¾ in., at London under the Thames River. The lining is made up of segments, bolted together, forming a ring, and the adjacent rings are also bolted together. Fig. 9 shows sections of the cast-iron lining used for the Central London Railway in London clay, which is a stiff non-water-bearing clay. The outside diameter of this tunnel is 12 ft. 6 in. and no secondary lining is used. Fig. 10 shows sections of the cast-iron lining used for the greater part of the Pennsylvania Railroad Tunnels in the silt under the North River at New York City. The outside diameter of this lining is 23 ft. and a secondary lining of concrete was used, making the total thickness of the tunnel lining 2 ft.

It will be noticed that the method of making the joints is different in the two tunnels shown. In the Central London Tunnel the surfaces of the flanges were not machined. The radial joints were made by packing a creosoted wood strip between the adjacent flanges and bolting them together. For the circumferential joints, on account of the necessity of sustaining the shield-ram pressure, the flanges were brought into contact, metal to metal, along the skin and a packing of yarn was placed at the bottom of the joint behind the bolts. The remainder of the joint was filled with mortar except where water was met, and here the usual mixture of sal-ammoniac and iron borings was packed into the joint. The radial joints were also finished with a pointing of cement or of rust caulking, as required.



DETAILS OF CAST IRON LINING FOR CENTRAL LONDON RAILWAY TUNNELS

FIG. 9.



DETAILS OF CAST IRON LINING FOR PENNSYLVANIA RAILROAD NORTH RIVER TUNNELS

FIG. 10.

In the Pennsylvania Railroad Tunnels all flange surfaces were machined so as to insure an exact bearing surface over the entire depth of the flange. A caulking groove about 1½ in. deep, however, was provided along the inside edge of the flanges. This groove was used to make the joint water-proof by filling it with rust caulking, and the bolts were water-proofed by packing grummets consisting of rings of yarn dipped in red lead under the heads and nuts of the bolts.

The main advantages of cast-iron lining are that it may be handled roughly without being damaged; that it may be procured in the shape

desired and in units of a size limited only by the facilities for casting and the weight that can be handled in the tunnel; that it may be erected and connected in a reasonable time, and that it may be made almost water-tight by caulking the joints and grummeting the bolts. The accuracy with which the faces of the flanges may be machined is nearly absolute and it is possible to erect iron thus machined to perfect shape. The efficacy of the lining, as a structure and as a water-proof envelope, then depends on its capability of resisting, without deformation, the stresses which come upon it.

Cast-iron lining of the type described forms an efficient structure in soils with a large angle of repose, if the diameter of the tunnel is not too large. The question of cost is not considered for the present.

The objections to cast-iron lining are as follows: The structure, in effect, is not capable of resisting stresses other than compressive. This is not so much due to the cast iron itself, which might be relied upon to carry a reasonable tensile stress, but to the method of fastening the segments together, which permits them to separate slightly under a bending stress. The result is that during construction in soil with a small angle of repose it is subject to various non-elastic deformations, and further the pressure of the compressed air causes, as has been stated before, bending stresses in the lining, producing distortion.

In soils of the character of the North River silt, deformations may occur due to temporary disturbance of the earth pressures on account of the pushing forward of the shield, particularly if the shield is driven ahead without taking in the full volume displaced. When such distortions occur, it is necessary to provide temporary bracing and support until the supplementary inside lining is in place, and this is expensive both in time and money.

In soil of moderately high angles of repose, immediately after the shield leaves the lining, this is surrounded with an annular space only partly filled with solid matter. This condition produces local pressures on the lining, causing it to deform; then again, when the air pressure is removed the conditions of equilibrium are changed and the lining is subject to further deformation.

The non-elastic deformation has another serious effect on the structure. The horizontal joints between the cast-iron segments, which are generally machined and expected to bear on the whole surface of

the flange, open up either on the inside or on the outside and thus not only is the strength of the ring as an arch greatly decreased but also the efficacy of the caulking is diminished. This is particularly important, because the caulking, in order to be effective, must be done under air pressure, and when the pressure is removed, deformation takes place, opening the joints and destroying the water-tightness. In a material such as North River silt, having tidal movements, an additional and periodical working of the joints may occur which will make the caulking ineffective, particularly in tunnels with no inside concrete lining. Leakage necessitates continuous expenditure for pumping, and in a material like North River silt, even a minute leakage produces a settlement of the tunnel, affecting its gradient.

The skin of the cast-iron lining has to support the thrust of the shield rams. On account of the construction space needed for the rams, their pitch-circle must be several inches inside of the skin-circle. This causes bending stresses in the rams and in the lining and, in large tunnels, results in bending and jamming of the rams, and breakage of the lining.

These considerations suggest the following changes in the design of cast-iron lining. The depth of the circumferential flanges should be made large enough to insure compressive stresses only in the lining or at least tensional stresses no greater than can be carried safely by the cast iron and the connection between the cast-iron segments.

The sections forming a ring should be connected so that non-elastic deformations cannot occur, and longitudinal ribs should be provided to support the thrust of the shield rams.

By constructing stress polygons for tunnels of various diameters it has been found that, if the pressure at the top of the tunnel is 4 000 lb. per sq. ft., the weight of the soil 120 lb. per cu. ft., and the angle of repose is 2° 52′, the maximum eccentricity, e, of the circumferential force in the lining, when the outside diameter lies between 12 ft. and 36 ft., may be expressed empirically by

$$e = \frac{d^2 \sqrt{d}}{480} \qquad (10)$$

where d is the outside diameter in feet and e is expressed in inches.

It is desired to make clear that the soil characteristics and weights of lining from which this formula is derived have been deliberately

chosen to accentuate the effect of a heavy soil together with a low angle of repose. The flanges and thicknesses of lining given in the following pages, therefore, are exaggerated. In soil of the character of North River silt, for example, the eccentricity will be found to be considerably less.

If the depth of the flange is made equal to $4e$, the tensile stress will not be greater than may be brought safely upon the cast iron, and the connections between the segments of the lining may be made strong enough to carry this stress. The depth of the flange will accordingly be as follows:

Outside diameter, in feet.....	12	18	24	30	36
Depth of flange, in inches.....	4	12	24	41	65

The inside diameter, Δ, is determined by

$$\Delta = d - 8e$$

By differentiation, the maximum value of Δ may be determined as 26.2 ft. In other words, in order to obtain a cast-iron lining not subject to non-elastic deformation under the conditions assumed, the inside diameter cannot be greater than 26.2 ft. Before this limit is reached, however, the size, weight, and number of the segments of the lining will have become unwieldy.

It is quite possible, however, to construct tunnels with a cast-iron lining having a flange depth less than that required to make the lining self-sustaining; in fact, the primary lining may be and has been made of a thin metal plate only. When the lining is not self-sustaining, it must be temporarily supported during construction and a secondary lining must be provided. The question of which method to adopt is essentially one of economy, but it must also be kept in mind that when the primary lining is not self-sustaining, the water-proofing becomes more uncertain and expensive.

It has been found, by plotting the weight of cast-iron linings of tunnels actually constructed in soils of this character, that the weight may be expressed by the equation, $W = 22d^2$, where W is the weight, in pounds per linear foot of tunnel, and d is the external diameter, in feet.

Precast Concrete Blocks.—As previously stated, concrete is not, except under special conditions, a suitable lining material for a shield-

driven tunnel, except in the form of precast blocks. In this shape it is well suited for tunnels of any diameter when the soil is dry and has a large angle of repose, and it may be used in tunnels of small diameters in water-bearing soil with a small angle of repose, providing it can be made water-tight; but, according to the foregoing stress determination, in the present state of the art it is not suitable under any other conditions.

The advantages of the precast concrete blocks are that they may be made of any shape and size desired, at a reasonable cost, and that they may be handled with ordinary care without being subject to serious damage.

The disadvantages of precast concrete blocks are, as a whole, the same as those of cast-iron lining, but to a greater degree; namely, they cannot resist other than compressive stresses and the water-proofing is uncertain in its efficacy.

It has been stated previously that bending stresses occur during the construction. These stresses the concrete-block lining cannot resist, even though interlocking arrangements are provided between adjacent segments, because it would be a practical impossibility to cast the blocks so as to secure the absolute fit necessary to prevent any motion in the joint. The result is, therefore, that the tunnel will distort and the joints open, when bending occurs, thereby throwing the full load on a small bearing surface either at the inside or outside edge, and producing a grave possibility of spalling off the edges of the blocks.

Owing to their bulk, the concrete blocks would have to be rather short, particularly in tunnels of moderate or large size. Consequently, the taper of the individual blocks would be slight, and it is entirely within the possibilities when the tunnel distorts and the joints open, that the block might be free to slide in under the external pressure, particularly when the outside edges are spalled off.

In order to make a tunnel lined with such blocks safe during the construction period, it would be necessary to make arrangements on the following general lines: To provide the blocks with steel rings securely fastened into them and during the time the air pressure was on to fasten tie-rods to these rings in the directions where increases of diameter might occur, and at the same time to support the lining with struts in the directions where the diameters might decrease. Such temporary support however would be expensive and interfere with

the work of construction. The stresses in the structure under normal air pressure might be taken care of by making the thickness so great that tensile stresses would not occur. As will be shown hereafter, this is only possible up to a certain inside diameter. The tensile stresses in the permanent lining might also be relieved by introducing proper permanent internal bracing of the lining, which, however, again would add to the cost of the structure.

The concrete blocks might be made reasonably water-tight by the addition of some water-proofing compound. The joints between the blocks could be water-proofed by means of water-proofing material, but in order to make such water-proofing efficient, it would have to be carried out with the greatest care at each individual joint before the next block was placed, thus retarding progress at the period of construction, when speed is of paramount importance for economy.

The efficacy of the water-proofing, however, would depend on the absolute prevention of distortion of the tunnel.

As stated above, Equation 10 expresses the eccentricity of the circumferential force. In order to avoid tensile stresses, the thickness of the lining must be not less than $6e$. This would require the following thickness of the lining:

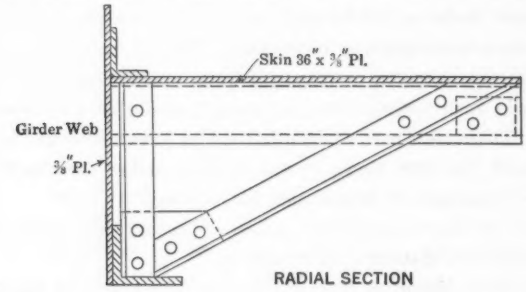
Outside diameter, in feet.....	12	18	24	30	36
Thickness of lining, in inches.....	6	18	36	61	97

It would appear, therefore, that the thickness of this lining becomes so great as to be impracticable when the outside diameter of the tunnel is more than 24 ft. Furthermore, the inside diameter should not be increased beyond 20 ft., because the inside diameter, Δ, is $\Delta = d - 12e$, and by differentiation, the maximum value of Δ is determined as 20 ft. In other words, in order to obtain a concrete-block lining not subject to non-elastic deformation under the conditions assumed, the inside diameter cannot be greater than 20 ft. unless inside bracing is provided.

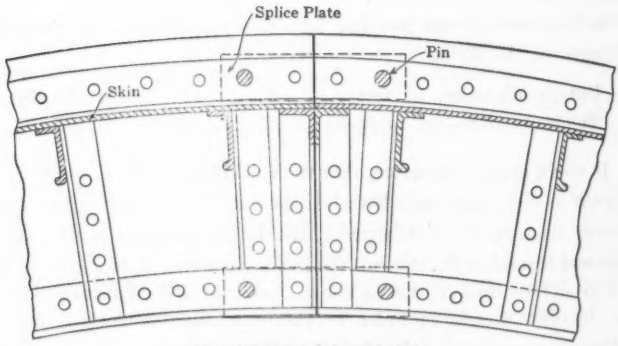
Structural Steel.—So far, all the usual materials of construction have been considered except structural steel, which up to the present time has been used for tunnel lining only to a very limited extent, in spite of its many apparent advantages. The most probable reason for this is that the standard material for primary lining for subaqueous tunnels, cast iron, has proved itself generally satisfactory, although in

soils having a low angle of repose it has become apparent that the limit of possible size has nearly been reached.

Steel has been used as primary lining for tunnels under the Spree and the Elbe Rivers in Germany. In both cases the steel lining was used as an envelope only, inside of which the permanent and supporting lining was constructed. Light wrought-iron plates were used for the old North River Tunnel, commenced in 1874. Steel has also been used



RADIAL SECTION



CIRCUMFERENTIAL SECTION

FIG. 11.

for a short length of the intake tunnel of the Hudson and Manhattan Railroad power-house at Jersey City, N. J. In this case, the steel lining was made of 13-in. ship channels, bent to the curvature of the tunnel and provided at the ends of each section with angle flanges, producing sections of steel similar to the usual cast-iron sections. These sections were erected and bolted together, following the procedure of cast-iron lining. This tunnel was provided with an internal wearing surface of masonry.

FIG. 12.—MODEL OF A STRUCTURAL STEEL SECTION FOR 18-FT. TUNNEL.

None of these types of steel lining is self-supporting but requires a secondary carrying lining. For the purpose of investigating the possibilities of a self-sustaining steel lining, the writers have, therefore, attempted to design such a lining. Fig. 11 shows its general character. It consists essentially of circular plate girders, spaced at intervals, supporting the steel plate envelope or skin. The girders are intended to be able to carry the forces that may come upon them without non-elastic deformation, but, as they necessarily must be brought into the tunnel in sections, they must be spliced. The compressive stresses will readily be transmitted through the machined abutting faces, and the tensile stresses may be transmitted through splice plates connected to the adjacent sections by means of tight-fitting pins or tapered dowels. Fig. 12 is a photograph of a model of a section for a tunnel 18 ft. in diameter.

The advantages of such steel lining are, first, that it may readily be made strong enough to carry without non-elastic deformation the forces to which it may be subjected, and, second, that it may be made absolutely water-tight by means of electric welding.

The principal criticism that might be made against the steel lining is probably that of possibility of corrosion. All the evidence, however, that so far has come to the knowledge of the writers appears to indicate that steel embedded in soil under conditions similar to those to which a tunnel lining is subjected does not corrode. More light on this matter would be desirable. Some evidence is afforded by the shield of the North Tunnel of the up-town tunnels of the Hudson and Manhattan Railroad. The skin of this shield consisted of a cylinder made up of two thicknesses of $\frac{5}{8}$-in. steel plate. The diameter of the cylinder was 19 ft. 11 in. and its length from cutting edge to end of tail was 10 ft. 6 in. This shield was erected in 1890 and was driven forward about 2 000 ft. in a little less than a year. It is not known whether the shield was painted or otherwise protectively coated before it started on its journey, but it is reasonably certain that any coating it may have had was rubbed off after traveling 2 000 ft. through the silt.

The work on the tunnel was abandoned in 1891, and the shield was left encased in the North River silt about half way across the river. Inside, the shield was filled with water and muck. In 1902, eleven years after the tunnel had been abandoned, it was cleaned out. The shield was found to be in good condition and, after repairs to the

machinery, was used to drive the tunnel the remaining distance across the river where it arrived and was dismantled in 1904, except the outer shell, which was left in place, the cast-iron lining being erected inside it. In other words, a steel cylinder with an unprotected surface of about 750 sq. ft. remained embedded in North River silt for eleven years without being impaired for use.

By making designs for a lining of this type for several different sizes of tunnels under the same assumptions as to soil characteristics

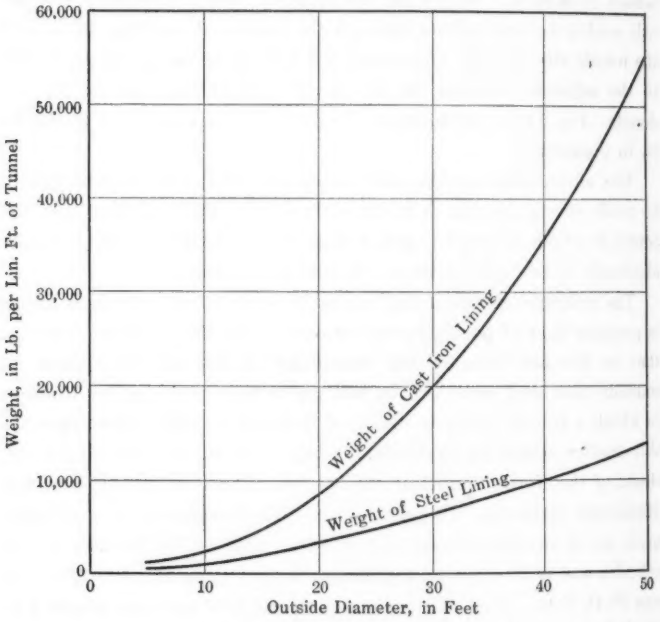


FIG. 13.

used previously, and by selecting the girder depth, expressed in inches, equal to the outside diameter, d, in feet, divided by 1.2, it has been found that the weight, W, of the lining, in pounds per linear foot of tunnel, may be expressed by

$$W = 4\,d^2 + 90d \qquad (11)$$

It will be found that weights of steel lining based on this formula, when compared with weights of cast-iron lining, range from 59% in the case of a 10-ft. tunnel to 26% for a 50-ft. tunnel.

Fig. 13 shows these weights plotted for tunnels up to 50 ft. in diameter.

9.—Secondary Lining.

The purpose of the secondary lining of a tunnel may be either to act as a carrying member, to produce a smooth inner surface, to give additional weight, or to protect the primary lining from corrosion. It generally consists of either brickwork or concrete. It has been stated before that in order to avoid troublesome deformations in a tunnel driven under air pressure, the primary lining should be designed so as to be able to carry the stresses to which it is subjected during the construction, as well as the permanent stresses, without non-elastic deformation. If that is done, no secondary lining is needed on account of strength and it might, if intended for that purpose only, be dispensed with.

As to the use of a secondary lining to produce a smooth inner surface, this is necessary when the tunnel is intended to carry water if the primary lining does not provide a smooth inner surface, for example, when the primary lining is constructed of metal. If the tunnel is intended to be used as a railroad or a highway, there does not appear to be any more reason to hide the metal construction than if the structure were a bridge.

10.—Cost of Tunnel Linings.

The previous sections of this paper have discussed the merits and demerits of various materials of tunnel linings from the point of view of serviceability without reference to the matter of cost. This feature, however, is of prime importance and often is a determining factor as to whether a tunnel is to be constructed or not, or if constructed, determines its capacity.

It was attempted, therefore, to formulate certain expressions by which the probable cost per unit of length of tunnels of any given size to be constructed through various kinds of ground, could be determined, if not absolutely, at least relatively.

The prices of labor and materials, however, usually are in a state of flux, and this is particularly true at the present time. Furthermore, the probable cost of labor and materials on any specific piece of work is so tied up with the local conditions which surround and attend that work that the conclusion was reached that such generalized and sweep-

ing formulas were more or less spurious and untrustworthy and might lead to erroneous results if applied without due caution and reserve.

It may suffice to repeat that, as far as the use of a tunnel is concerned, the internal cross-section is the measure of its capacity. As far as the stresses which will exist in the lining are concerned, the outside diameter is the ruling factor. Hence, in comparing one type of tunnel lining with another for tunnels of the same internal cross-sections under the same external conditions of ground pressure, assuming that the various linings compared have been designed so that the tunnel shall have equal strength in each case, the following factors should be brought into the comparison:

1.—The volume and cost of the excavation;
2.—The weight and cost of the lining material;
3.—The probable rate of advance;
4.—The permanence of the lining material;
5.—The possibility of making the lining water-proof.

11.—Conclusions.

From the previous discussion the following conclusions are reached:

1.—When the characteristics of the soil through which a tunnel is to be built are known, it is possible to determine the stresses in the tunnel lining.

2.—In order to obtain direct compressive stresses only in the lining of a circular tunnel, the diameter of the tunnel must be limited to a certain value which varies directly as the angle of repose of the soil in which the tunnel is embedded.

3.—In soil with an angle of repose producing bending stresses in a circular tunnel, it is possible to reduce, and sometimes to eliminate, the bending stresses by making the shape of the tunnel elliptical.

4.—If the total vertical downward forces are less than or equal to the total maximum passive upward forces the tunnel will not sink.

5.—If the sum of the total downward load and the frictional resistance is greater than the total active upward force the tunnel will not rise.

6.—The pressure of the compressed air in the tunnel during construction produces bending stresses in the lining.

7.—The shoving of a shield through plastic soils without taking in the full volume displaced by the shield induces temporary pressures in the ground which tend to deform and displace the lining.

8.—The lining should be designed so as to be able to carry not only the permanent stresses but also the construction stresses, which include bending, even though the permanent forces produce compressive stresses only.

9.—Consideration should be given, in each specific case presented, to the advantages and disadvantages, from an engineering viewpoint, of making the primary lining the entire carrying member, or of supporting the primary lining when and where necessary until the secondary lining has been placed.

10.—Up to the present, the rate of progress of a shield-driven subaqueous tunnel has been a function of the diameter of the tunnel. For each variety of ground this relationship is different, but in general the rate of advance increases rapidly from zero diameter up to a diameter of about 10 ft. and then decreases with increase of diameter.

11.—In soils with a low angle of repose, for any specific case presented, there is a limiting inside diameter (which may be determined for that case) beyond which the primary lining, whether of cast iron or of concrete blocks, cannot be designed to stand without internal bracing.

The subject covered is one on which there is still much difference of opinion and doubt. The writers hope that these notes may give rise to a discussion on the design and construction of tunnels which will help the engineer who has to deal with this most fascinating work.

DISCUSSION

Mr. Meem. J. C. MEEM,* M. AM. SOC. C. E.—This paper has been carefully prepared and contains much of value in the way of data and conclusions. In the speaker's judgment, however, it also contains, unfortunately, serious misconceptions as a basis for some of the conclusions given, especially, first, as to the characteristics of the Hudson River silt, and, second, as to the pressures exerted by it and other subaqueous soils.

First, as to the characteristics of Hudson River silt: Referring to the fact that a shield can be pushed into this silt without opening the doors, the authors state:

"That this particular soil is essentially a viscous fluid. Such a thing could not be done in clay or sand or a mixture of such. Observations on the jack pressures used to start an actual shield in movement through the silt confirms, when analyzed, the fact that the material has an angle of repose of less than 3 degrees."

Second, as to pressure, the authors state:

"This was done by analyzing many hundred observations of the external pressures on the tunnel lining, obtained by means of specially constructed and highly sensitive pressure gauges inserted in holes in the skin of the cast-iron lining."

Taking up first the alleged misconception as to characteristics, the error is probably due to two principal facts: That such samples as can be obtained and observed are apparently of an aqueous rather than a stable nature, and the further fact that soil into which a shield may be pushed without extraordinary pressure or without opening the doors points to soupy or at least a viscous fluid.

Although it is true that this cannot be done in sand or gravel, it can be done in clay or in a mixture containing a large percentage of clay and a small percentage of fine sand. In fact, this is the composition of the soil under the Hudson River below the first layer of fine organic deposit. In filling a void under a pier foundation under the United States Post Office recently, a specially constructed jack was used by means of which clay amounting to about 1 500 lb. was jacked into the void under a pressure of about 1 200 lb. per sq. in. It was found that sand up to 40% could be mixed with the clay without interfering with its susceptibility of flowing under heavy pressure. When it is realized that a shield can be jacked into the stiffest clay or even into solid lead, under proper conditions, it should be understood that soupiness or extreme viscosity is not essential to this condition, but its visualization is only a sop thrown by and to our finite minds in order better to comprehend its action.

* Brooklyn, N. Y.

Mr. Meem.

Assuming, for instance, that a shield with a closed frontal area of 350 sq. ft. advances into this soil under a pressure of 1 400 tons, and that 700 tons are required to overcome the frictional resistance, the force displacing the soil is 2 tons per sq. ft. While with all allowances it is probably much greater than this, it may be assumed that 2 tons is the minimum. If, now, a puddle of clay is made up in a pit or large vat and a pressure of 2 tons per sq. ft. is brought to bear upon it at the base of a hollow pipe set in the mixture, it will be found that nothing short of a pretty stiff mixture will resist the pressure so applied.

Another fallacy is that compressed air changes the texture, or at least the density, of the soil to which it is applied, thereby hardening it or stiffening it. As a matter of fact, it simply drives out the water and that the water can be driven out shows that in its normal state the pressure due to it is independent of that of the soil.

It should be realized that air does not support the soil, but prevents disintegration by driving out the water or holding its inflow back. In its normal bed, with no percolation or flow of water through it to disintegrate and soften it, this soil probably would appear exactly as if under air pressure, the only difference being that the air replaces the water.

The fact that the old Hudson Tunnel was driven for a long distance under the Hudson River without a shield—with an open face—and that the material under air stood up well and was very stiff, and that the bottom did not tend to rise, should convince the most skeptical that this silt has not normally the soupy or aqueous properties with which it is generally credited. There is also no reason to doubt that if this soil was as soupy as it is sometimes conceived to be, the shield could not be prevented at times from running ahead under its own air pressure.

As to the angle of repose which is given by the authors as being less than 3°, it is impossible for the speaker to conceive of a soil having an angle of repose anywhere near as small as 3° without being aqueous, and, therefore, having no angle of repose. The error of crediting aqueous materials (which can have no angle of repose, just as water has none) with flat angles of repose is frequently made. In all probability this silt in its natural bed, when not subject to the influx or outflow of water, will stand at an angle nearer 60° than 3°; it is even probable that if the bed of the river is dredged below the top layer of organic deposit, the silt will be found to stand at an angle of at least 45 degrees. This, however, will not necessarily determine its angle of repose in any case, for, although the water pressure tends to prevent the disintegrating outflow of water through the soil, it also keeps its surface in a softer and more pliable condition than if unexposed in its natural bed. The best test to deter-

Mr. Meem. mine its normal angle of repose is to note its action under compressed air. In tunneling in subaqueous sand, for instance, it will be found that under compressed air its action is similar to that of a normally dry sand under normal air pressure and that it will have to be sheeted and braced in the same way; further, its angle of repose is the same under both conditions.

In tunneling in clay or silt composed of clay and fine sand (and there are numberless instances of this having been done without the use of a shield, especially in the Lake cities), the same relative conditions will prevail, except that the cohesive qualities of the soil act in conjunction with its arching properties, rendering sheeting and bracing less necessary than in sand. That is, in the speaker's judgment, the same sheeting and bracing would be necessary in subaqueous soil under air as would be required for the same kind of soil under normally dry conditions. Observations of the tendency of the soil to break down under vertical cutting should determine in both cases the normal angle of repose. As heretofore stated, the speaker's judgment is (which in this case, perhaps, may be only an educated guess) that this angle will probably be about 60 degrees. This will be referred to later.

As to the distortion of the tunnel, it is somewhat difficult to believe that an elongation of the vertical axis actually takes place, but if (or where) this is authenticated and not noted as the result of unchecked observations, it may be accounted for as follows: The tube is surrounded by a more or less aqueous or soupy envelope between it and the more stable material. This being heavy, it tends to flow to the bottom and thus keeps the tube from subsidence, while the greater resilience of the material displaced sideways reacts more quickly than the vertical displacement (which has more room for expansion) and thus elongates the tube in this direction.

As a matter of fact, however, the records show that the Pennsylvania Tunnel settled during construction nearly 4 in. and that there was a tendency for the sides to press out into the voids left at each side by the passage of the shield. That is, its history seems to be one of vertical props and lateral tension bars—also, in spite of these, of occasional cracked plates—and this is the history of virtually all tunnels, except those backed up by some solid filler at the sides which may be supplemented by grout. In the Battery Tunnel, on Joralemon Street, Brooklyn, N. Y., where air was not used, the grout immediately flowed to the bottom and, although it prevented the tube from settling, it left voids at the sides into which the plates at once spread. This resulted in the cracking of many of the crown plates, though it is interesting to note that these cracked plates carried (when the sides had found solid backing) the load which had apparently cracked the good plates.

Mr. Meem.

The apparent remedy is, in all cases, to apply some solid filler, such as clay or gravel, directly after the passage of the shield and follow it with grout. This will tend to prevent distortion, eccentric loading, and other ills now attendant on construction.

Much importance appears to attach itself to the fact of the rise and fall of the Pennsylvania tubes, due to the fluctuation of the tide. This is probably due to the resilient action of the more or less compressed material and not to any condition of fluidity. While, from entirely different causes, the fluctuation may be compared with the action of a tube embedded near the surface in a mass of solid iron which would fluctuate with the temperature changes of the iron, as well as with its expansion and contraction, if due to pressure and resilience exerting the same stresses as temperature changes.

What the speaker considers to be errors in pressure are due largely to the interpretations of some of the characteristics of the soil, as just noted, but principally to the interpretation of the pressure-gauge readings. He has often pointed out the fallacy of attempting to interpret the pressure on the whole area of a structure by pressure readings on gauges through orifices in the lining. To attempt to do this in normally dry soil is comparable to attempting to estimate whether the chamber of an hour-glass is a cubic foot, a yard, or an acre by placing one's fingers or a gauge over the orifice, when it is obvious that orifices of the same area will show the same pressure for all sizes of chambers. Gaugings through linings of structures in subaqueous soil are almost equally misleading, for while the gauge may show full pressure due to the hydrostatic head of water in each of a dozen instances, the tunnel may be resting on solid soil bottom from which no pressure results on the bottom side and a separate and distinct pressure (to be noted later) from the soil at the top.

If, however, the gauges indicated full hydrostatic pressure and it was distributed over the whole area, then the stress computation would be simplified, though the actual problem would be greatly increased, being principally the prevention of flotation. This latter, of course, would occur when the upward pressure exceeded the downward pressure plus the weight of the structure. It would not be dependent in any way on the flatness of the angle of repose. Again, if, as is sometimes erroneously suggested, the soil exerts a fluid pressure equivalent to a fluid of a specific gravity of 1.6 (or an aqueous pressure of 100 lb. per sq. ft.), then the air pressure required, for instance, at a depth of 90 ft. would be about 60 lb. instead of 38. As a matter of fact, the air pressure required has usually been below the normal hydrostatic head in Hudson River tunnel operations.

In the case of these tunnels, had the pressure on the bottom been as was shown by the gauges, this bottom would undoubtedly have come up under the air pressure used—particularly in the old tunnel.

Mr. Meem. Where a bottom gauge shows a pressure greater than the normal hydrostatic head, it is probably due to settlement of the tube pressing the gauge into the soil, and when the gauge at the top or sides shows a greater than normal pressure it is due to the blanket-like action of the soil, which may press on an isolated gauge with greater pressure than the unit pressure of the area impinged upon.

The speaker understands that in many cases the soil into which these gauges were set had first to be stirred into activity before the

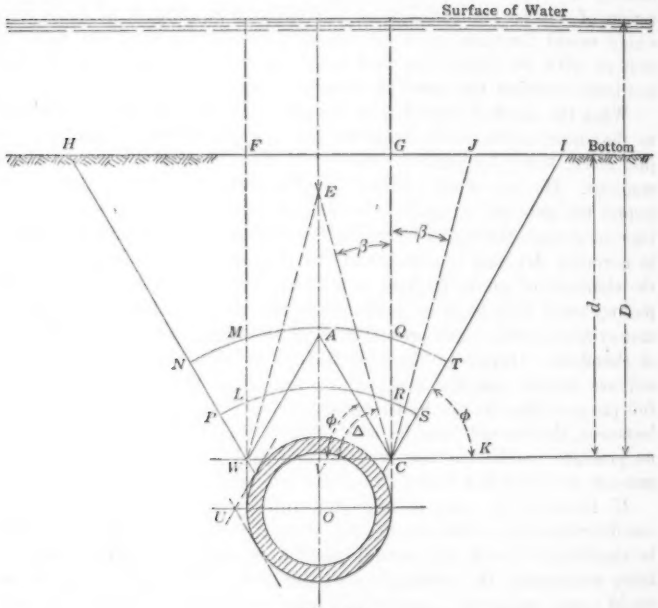

FIG. 14.

gauge would become operative; he has also heard of instances in other operations, where gauges were juggled to make them "read correctly."

In fine, the speaker believes these gauges will not show correctly anything except the hydrostatic head, which is always known, while the actual area of the pressure, as well as the pressures of the soil, will be left absolutely undetermined. He believes, further, that better results can be had from small models reproducing relative conditions and giving pressure readings over full areas than from interpretations of all the gauge pressures ever made.

Mr. Meem.

Under these conditions, normal and eccentric pressures, hydrostatic pressures, buoyancy, etc., can be determined definitely and correlated to the conditions of service.

The speaker has always held that pressures on walls, trenches, tunnels, etc., can be determined from the practical and rational interpretation of well-known or observed physical laws. His own method of determining the pressure on tunnels is as follows:

First, it should be obvious that soil and water cannot exert pressure on the same area at the same time. If, for instance, a column of impervious clay stands on the bottom of a tank full of water, there is no water pressure on the area occupied by the bottom of the column. The weight on the tank bottom then is the area of the water pressure less the least cross-sectional area of the column plus its weight, which is equivalent to saying the weight of water plus the weight of the column less the weight of water displaced.

If the column of clay is suspended so that it is in contact with, but does not stress, the tank bottom, the weight on the tank bottom will then be the weight of water over the whole area less the area of the column.

If mud or soil is placed in a tank filled with water and the tank is deep enough, the soil will eventually reach sufficient depth to arch and relieve the bottom of a part of its load. This can be demonstrated by any one on a small or large scale.

Referring to Fig. 14:

Let ϕ = the angle of repose of the soil in its normal bed;

$$B = \frac{90 - \phi}{2} = 45° - \frac{\phi}{2};$$

$$A = \phi + B = 45° + \frac{\phi}{2}.$$

If, for a moment, it is assumed that $FWCG$ is a sheet-pile cofferdam and that IC is the plane above which all soil would slide away if left unwatered and unprotected (that is, the unwatering should precede the operation of determining the angle of repose by allowing it to slide), then it must be assumed that the weight of some of the soil in the area GCI is transmitted as thrust against GC and some of it rests on the plane IC.

The speaker arbitrarily assumes that the plane JC bisects this area and that all the area GCJ exerts its pressure against the wall GC.

Reversing the condition, as shown, all the weight of ACV must be carried by the tunnel, by the same assumption as before, and all the weight of ACE also is carried by the tunnel. Above that, all the soil has become self-sustaining by reason of the development of

Mr. Meem.

its arching properties. This may be shown more clearly by the lines *PLRS* and *NMQT*, within which are developed the self-sustaining arch stresses. The curve *NMQT* is drawn so that the area *WMQC* will equal the area *WEC*.

While it is believed that the depth *EV* is greater than necessary to develop the sustaining arch, the speaker has always used this figure, as noted.

That is, although the soil will arch itself along the lines *NMQT*, it may probably require a height of soil above *WC* equal to *VE* in order to relieve the tunnel of the stress of the soil outside *WEC*, or its equivalent.

This height *VE* is found to be $\frac{L}{2}$ tan. $\left(45° + \frac{\phi}{2}\right)$, or $\frac{L}{2}$ tan. Δ, where L is the outer diameter of the tunnel.

Assuming, then, that the pressure of the soil is thus accounted for independently of the water pressure, it is evident from the foregoing that it is necessary to consider water pressure due to the full hydrostatic head, but only for that percentage of the area not pressed on by the soil.

It is probably not far from a correct assumption to state that this area is 30 and 40% of the whole, but as a safe factor the speaker has always taken 50% of the total as the practical area of the water pressure.

The pressures at the sides and bottom must also be considered. The side pressure (except during construction, when there may be an increased pressure due to the surge following the passage of the shield) is the thrust of the area between the tunnel and intersecting planes parallel to the planes of repose and tangent to the outside of the tube at the upper and lower quarters. It may be computed approximately as the weight of the soil in this area divided by the tangent of the angle of repose, that is,

$$P_s = \frac{A_s W_s}{\text{tan. } \phi}.$$

In view of the fact, however, that this pressure is much less than the vertical pressure of the soil, and that in its final position after construction the soil tends to resist displacement of the structure rather than to exert unbalanced pressure, the structure should be designed to resist at any point the maximum static pressure of the soil and water combined. Such allowance as in the judgment of the engineer may be necessary can be made for the exigencies of construction, but the effort should be directed toward reducing those exigencies rather than by adding a large percentage to the size, and thereby to the cost of the structure.

Mr. Meem.

The maximum pressures are thus found to be:

$$P = \frac{L}{2} \tan. \measuredangle \times \frac{L}{2} W + \frac{62.5}{2} D L$$

$$= \frac{L^2}{4} W \tan. \measuredangle + 31.25 D L$$

in which

P = total pressure on upper half of tunnel;
L = outer diameter or greatest width of tube;
W = weight of soil;
D = depth of water;
d = depth of soil to tunnel.

This is true for those cases where VE is less than d.

Where VE is greater than d:

$$P_2 = L d W + \frac{62.5}{2} L D$$

$$= L (d W + 31.25 D).$$

Where VE is so shallow that the possibility of full hydrostatic pressure is present, more especially during construction, then P may equal $L \times 62.5 (D + L) = P_3$.

The engineer is always justified in designing to meet the maximum pressure as between P_2 and P_3, but he is not justified in designing against a pressure represented by the total weight of soil plus the total weight of water, nor is he justified in assuming an aqueous pressure due to liquid soil of greater specific gravity than water, when the fluid medium is water.

An interesting photograph (Fig. 15) shows the difference in soil in its normal bed and exposed. This soil underlies Trinity Place in New York City back of Trinity Churchyard (which acts as a reservoir for it) and is the nearest approach to quicksand the speaker has ever seen. When exposed it is almost fluid and flows freely. A man will sink into it to considerable depth and it can only be handled by compressed air or elaborate methods of drainage. When drained it will stand at an angle steeper than 45°, and piles driven into it (when undrained and in its normal bed) only a few feet below the base of operation will bear, after some initial settlement, a sustained load of from 10 to 25 tons. The photograph shows 12-in. steel sheet-piling which was driven into this soil and met with such resistance due to stiffness and tenacity that it was distorted as indicated. The actual material into which it was driven is the same semi-fluid soil as that shown in the photograph. A 14-in. pile bearing some 6 ft. below the level shown is sustaining its portion of the surface and sub-surface structures with the ordinary street traffic, including trolley cars.

Mr. Meem. As to the question of rust of steel or iron disintegrating the exterior lining of subaqueous tunnels, the speaker believes there will be no deterioration whatsoever, or at best a small film of "protective rust." Since rust causes approximately tenfold expansion and any expansion will cause pressure, the initial rusting, if it takes place, will be pressed upon the metal and act as a protective coating. In this connection he presents Fig. 16, a photograph of light tunnel plates taken from the 15-ft. Greene Avenue sewer built on Hanson Place, Brooklyn, N. Y., in 1893, by the Anderson and Barr pilot method. They were removed in 1917 by the Degnon Contracting Company, and after 24 years in normally dry soil show almost no deterioration from rust. It is interesting to note that where voids were left by the moving of the plates at the rivet heads, these voids have filled with rust. This tends to show what the speaker believes to be true, that rust, like grout, will not expand into the normal voids of the soil, but will fill those artificially made.

In conclusion, the speaker believes that the normal pressure on the tunnel in place is definite and determinable and that the exigencies of construction should be eliminated as far as possible by following the shield with an envelope of clay or gravel, supplemented, if necessary, by grout, and that if this is done an allowance of not more than 25% should be made for contingencies.

The speaker does not believe that large sums of money should be expended to guard against remote contingencies, such as, for instance, the possibility that a tunnel if built even of solid cast iron could be displaced and probably disrupted by driving near it a larger and heavier tunnel.

It is essential that judgment based on observation and experience be allowed to become an important factor in all designing. When it is realized that the Battery Tunnel with, in some instances, only a 9-in. cast-iron ring with 2 in. of concrete in addition, and the McAdoo tubes with cast-iron lining only and no concrete, are permanent and stable structures and will always remain so—for even they meet with a large margin of safety the demands of adequate design for tunnels in place—engineers should endeavor in subaqueous designing to analyze the conditions that render them stable and not utterly disregard these plain facts.

For a concrete tunnel 30 ft. in diameter, 100 ft. at bottom below the water and 20 ft. at top below the bottom of the river, we would have 153 750 lb. per lin. ft. for silt weighing 100 lb. per cu. ft. Adding 25% for contingencies = 192 500 lb. At 600 lb. per sq. in. for concrete this calls for a 14-in. ring. The speaker, of course, would not even suggest the building of a 30-ft. tunnel with only 14 in. of concrete, but he does not doubt that the 14-in. ring in place would be absolutely stable. He believes that it would also not be economically

FIG. 15.—ACTION OF QUICKSAND ON 12-IN. STEEL SHEET-PILING.

FIG. 16.—EFFECT OF RUST ON STEEL PLATES.

sound to increase this thickness to more than 30 in. under all conditions, including the safeguarding driving shield construction. Mr. Meem.

Finally, the speaker wishes to state his belief that fully 95% of the tunnel failures are due to improper backing of the sides. This also applies to back-filled structures.

E. G. HAINES,* M. AM. SOC. C. E.—To avoid the necessity of any one else feeling called on to make the announcement, the speaker will state at the outset that although he has had experience in the construction of shield-driven tunnels in dry ground, and a limited experience in subaqueous tunneling, the latter has been confined to a position back of the lock, and he has not had any experience in compressed air. Nevertheless, he has had considerable experience with silt, and as this bears on some of the questions at issue in the paper, the following is submitted for consideration in this connection. Mr. Haines.

The authors state that the material encountered beneath the Hudson River is a silt with an angle of repose, so called, as low as 3° from the horizontal. The speaker assumes that the statement is intended to be taken literally, and that the authors imply that all the material above the bottom of a tunnel, lying also above the angle of 3° from either side, is, in its natural state, in an unstable condition, and exerts an influence and pressure on any body submerged therein. The speaker submits that were these conditions true, it would be absolutely impossible to build a tunnel within the material, to dredge and maintain a channel therein, or even to anchor a vessel in it.

When encountered in excavation, silt is usually called clay, because of its general appearance, and much trouble often ensues because of the error in classification. There is a great difference between the two materials, both as to origin and action. Clay is the result of decomposition of the feldspathic rocks, and such grit or sand as it contains is in the nature of an impurity and small in quantity. Such voids as it contains are not connected and it forms, as found in its natural bed, an almost perfect barrier to the passage of water. Water standing on it, or flowing over it, does not penetrate to any depth, but makes the surface slippery, like grease. It is plastic, however, and under sufficient pressure will flow without losing its cohesive quality, or developing fracture planes. Silt, on the other hand, is the result of mechanical disintegration of rock, in other words, it is rock flour, and contains only a limited quantity of clay to give it cohesion. It is practically all granular, and its density is due to its extreme fineness, the manner in which it was deposited, and the pressure to which it has been subjected. Silt has a relatively large percentage of voids, and these being connected, water passes through it as readily as sand. If, however, the water passes through under unbalanced pressure, or

* Brooklyn, N. Y.

Mr. Haines.

at too great a velocity, its low cementing qualities are quickly lost and it is converted into a mass closely resembling heavy paint, in which the water, as a vehicle, carries the grains in imperfect suspension. Silt will also flow under pressure—under certain conditions it will move by reason of its own dead weight in the same manner as other soils—but when this occurs the entire moving mass is broken up and all cohesion is lost.

The speaker has examined and compared samples of Hudson River silt with samples of other silts from different localities near New York City, both in dry ground and in other streams leading into the tidal waters in that locality, and he finds no material difference between the various samples, except such as might naturally be expected. Silt, being the finer pulverized material from the rocks in any river valley, differs in the mineral it contains in different localities. It also differs in fineness, and the silt of the Hudson River shows extreme fineness—it is finer than any other which the speaker has examined. Nevertheless, in their natural position, undisturbed, even though submerged beneath or filled with water, silts possess considerable cohesion and form a very compact mass.

Whenever one speaks of cohesion in soils, speaking first of dry ground, he is met with the exclamation "sand!", and speaking of wet ground, with the word "silt". Now, it is submitted that there is nothing mysterious or peculiar in the action of either sand or silt. In the condition found in Nature they both possess cohesion to quite a large degree. In fact, the cohesive element is far stronger than any other element tending to resist displacement—stronger than all others combined. Sand and silt stand at almost opposite ends of the entire range of materials classified as soils, one being the quite dry granular element, and the other the wet, compact plastic mass. The speaker presents photographs illustrating cohesion in each.

Fig. 17, reproduced from a photograph taken in 1916, shows a bank of sand cut vertically at the side of a subway excavation, where it crossed the line of a small drift excavated about 1905. This drift is beneath the surface of Fulton Street in Brooklyn, at Borough Hall, and was built for the diversion of a sewer, in connection with the old Brooklyn Subway in Joralemon Street. The work was done by J. C. Meem, M. Am. Soc. C. E., for Cranford and MacNamee, and was revealed by the excavation of the Clark Street line of the Dual Subway System. The photograph was presented to the speaker by Mr. Willis Thompson, Section Engineer for the Transit Construction Commission. It will be noted that above the poling boards of the drift there is a well defined arch in the sand. Mr. Thompson states that the material lying above the poling boards was finely pulverized, and that above the loosened material, as shown by the photograph, was a void, about 2 in. in width, between the solid and loosened ma-

FIG. 17.—WELL-DEFINED ARCH ACTION IN SAND IN SUBWAY EXCAVATION.

FIG. 18.—CHARACTER OF SILT IN SUBWAY EXCAVATION, NEW YORK CITY.

terial. The material through which the drift was driven was sand and gravel, rather loosely held together with cementing material, the firm overlying strata being fine sand. The top of the drift was about 8 ft. below the surface, and the point where the photograph was taken was approximately beneath the rail of the street surface railroad above. The width of the drift was 4 ft. and the rise of the arch exactly one-half the span. Notwithstanding the fact that this material had been carrying the street surface traffic of the busiest trolley line, probably in the world, for more than eleven years, the arch of sand had retained its integrity throughout. This photograph is a very good illustration of the cohesive strength and arching action always present even in relatively dry sand, as found in Nature. Mr. Haines.

Fig. 18 shows the side of a subway excavation in silt, a material called "clay" by the workmen; its character is clearly indicated. In the lower right-hand corner some large blocks may be seen and the marks of shovels and picks on the face of the bank are also apparent. The exposed face exceeded 10 ft. in height and was dressed carefully to line in advance of driving the sheathing planks. The heavy black line crossing the exposed face diagonally is organic matter and measured at its widest point about 12 in. The material both above and below the organic matter was silt. Samples were submitted for analysis, and it was found by using a micrometer under a microscope that the bulk of the material had a grain size of less than 0.01 mm., or even finer, to pure clay. Very few particles measured to 0.05 mm.

The extreme fineness of this material may be better gauged when it is stated that compared with it Portland cement is a very coarse material, and yet this silt, in turn, compared with Hudson River silt is quite coarse. Examination of the material shows that it is rock flour, with just sufficient clay to make it plastic. After dressing the bottom of the cut to grade, tests were made with a compression apparatus, by which the pressure on a single square inch of surface was determined, and it was found that, with a pressure of 50 lb., the instrument would hardly make an impression on the surface.

Notwithstanding the compact, solid nature of the material as exposed, after the completion of the excavation to grade, following a succession of rains, it was found that the workmen, in building the forms for concrete, churned it up into such a liquid state, that an average of over 1 ft. in depth had to be removed before it was possible to build the concrete bottom of the subway structure. Since the completion of the structure there has been no evidence of any settlement whatever.

Being carried in suspension and deposited by water, it is natural to suppose that silt would be in its softest state, and have the lowest angle of repose, at the time it was deposited, yet attention should be called to the fact that the angle at which this particular silt was

Mr. Haines.

deposited was 30°, as shown by the line of the organic matter. Furthermore, it must have remained at that angle for a long time, to allow of the accumulation of the organic matter, and, later, the deposit of silt above. It will also be noted that the angle of stratification repeats in the upper layer of silt.

The above example is of silt lying inland and extending so close to the surface as to be unaffected by ground-water, except that it is kept moist. The same material, however, was encountered some distance away, close to the East River, at a point where the street surface was about 6 ft. above mean high water. Ground-water level was about 1 ft. above mean high water. The excavation at this point was about 30 ft. in depth, about 20 ft. at the bottom being in the silt. The material was excavated in the usual manner by keeping the sheathing footed, and pumping from a sump to which several open ditches led. The bottom was at all times easily softened by working on it, but was readily dressed to grade. After the completion of excavation, work was suspended for an entire winter, and the cut was allowed to fill with water, which rose to a depth of more than 20 ft. The water stood in the cut for more than three months. It was then pumped down slowly. There was no evidence of great pressure, no bulging of the sheathing, and no rising of the bottom; in fact, nothing to indicate that the banks had been softened by the water, although all of it had passed in through the sides and bottom of the cut. There was a failure of each bank, as shown by cracks which developed in certain buildings, but the disturbance was limited to a distance equal to the depth of the cut, and even this was probably partly caused by the weight of the buildings.

The speaker has recently had opportunity to observe the action of water in the silt of the low lands adjoining the Passaic River, which not long ago flooded adjacent ground to a depth of several feet. At a distance of about 200 ft., observation in test pits showed that the ground-water level followed that in the river, receding, in some cases, at the rate of more than 1 ft. in 24 hours. Not far distant, however, are certain clay pits, with vertical banks, in which pools of water have stood to a depth of several feet for a number of years.

The authors state that the Hudson River silt is a material varying in weight with the depth below the river bottom, with an average weight of 108 lb. per cu. ft., and containing 55% of water by volume. The speaker believes that the latter statement is based on errors of observation, and that the error in the statement may be readily shown in this way: If every individual grain of the material were a perfect cube, and in contact with other grains only at the acute points of the corners, there would still be only 50% of water contained in the mass, and to increase that quantity it would be necessary that the faces of all the grains be made concave, or else that each individual grain be

carried in actual suspension. These conditions, it is known, are not true. As a matter of fact, the silt of the Hudson River is a most compact mass, due to the extreme fineness, the long interval of time during which it has been deposited, and the extreme weight which it carries on its upper surface. Mr. Haines.

The authors state that the material is readily compressed by an additional height of tide, and that the compression can be measured. From this, it is argued that the material is in a semi-fluid state. The speaker submits that the statements made directly contradict that supposition, for a fluid being practically incompressible, it is evident that the compression made by the tide is due to the elastic qualities of the silt considered as a solid. This is not peculiar to silt, but is true of all solid bodies, as under sufficient pressure, there is a reduction in volume, or, stated in another way, the volume remaining constant, the greater the pressure the greater the weight. This is confirmed by the authors' statements of increase of weight with depth.

The difficulty encountered in driving a shield through silt is due, not to the condition of the material itself, but to the conditions created by the driving of the shield. There is a vast difference between soil filled with water and water filled with soil. The second condition can readily be created from the first, by disturbance and erosion. The first condition cannot be created from the second, except after a very long interval of time with the water quiescent and after being subjected to a great deal of pressure. The process of driving a shield is such as to create a disturbance in the material. In dry ground, and the speaker believes also in wet ground, it is uncommon to use all the jacks for driving the shield. The result is that while the shield moves forward it is not, at all times, parallel to the line and grade of the tunnel, and has a tendency to disturb somewhat more material than that indicated by its outside perimeter. There is also a small space behind the shield which, in any case, requires to be filled. Due to the fact that water is always entering the tunnel near the bottom, or air passing out near the top, or both, there is constant change taking place by erosion, inward at the bottom and outward at the top. This has a tendency to bring to the bottom particles of the silt, which tends to restore the bearing at that point, but the erosion at the top is outward and with the pressures at the sides and bottom, there is naturally a tendency for the tube to rise. These conditions are, of course, much aggravated when the shield is driven without taking in the silt. In that case, there is an entire rupture of the overlying material for some distance on each side. As the rings are made tight, however, the action of the silt is downward at all points and equilibrium is restored. There is then a tendency to settle and spread laterally until resisted by the compression of the silt. These simple facts account for all the distortions and stresses indicated, as well as

Mr. Haines.

any theory, such as Rankine's conjugate stresses, which is based on conditions not actually found in practice.

The speaker, a number of years ago, had occasion to do considerable dredging in various tidal waters around New York City. The material removed was often so soft that it was difficult to hold it in the buckets, and even in the scows, and loads were lost a number of times by not being able to make the traps in the bottom close securely enough. Notwithstanding this, careful soundings taken after the dredging showed that the sides of the dredged area were very abrupt. In some cases the top portion outside of the dredged area could be observed at extreme low water. This material, which was mud and sand, was removed with a clam-shell dredge, and it was found that the depth of dredging was controlled by the compact silt beneath, for which that type of dredge was unsuited, as it would not penetrate to any extent into the silt.

There is nothing to indicate that the action of soil beneath water is much different from that of dry ground. The reason this condition might be expected the speaker will not repeat here, as it is already on record in his discussion of a paper on the "Bracing of Trenches and Tunnels",* presented by Mr. Meem. He would state, however, that in the past twelve years he has found nothing to contradict the suggestions he then made, but much tending to confirm them.

The authors state that when the Hudson River silt is subjected to air pressure, the silt has the nature of a stiff clay and its consistency may readily be varied by changing the air pressure. The speaker submits that this condition is due, not to the presence of the air, but to the absence of the water, and were it possible to exclude the water from the silt, or even to balance it exactly at all points, so as to restrain the water and prevent any erosion by reason of its passing through the silt, that most of the difficulty in subaqueous tunneling would be overcome. For that reason, while he has no desire to enter into any controversy as to the merits of different tunneling methods, he suggests that the proposition of using a shield in which it is possible to control, within narrow limits, the pressure at different heights, is decidedly interesting and a step in the right direction, and if the control could be extended a short distance, back to the point where the rings are caulked, the danger of soil disturbance from erosion would be largely eliminated. Whether the practical difficulties in the way of accomplishing this are too great to be overcome the speaker does not feel qualified to state, but if it is possible, then a shield-driven tunnel in the Hudson River silt might very readily be built much as one would conduct such operations in the same material in dry ground.

* *Transactions*, Am. Soc. C. E., Vol. LX (1908), p. 27.

PHILIP AYLETT,* ASSOC. M. AM. SOC. C. E. (by letter).—Coming as it does on the eve of the construction of another great tunnel under the Hudson River, and in the midst of professional discussion involving similar problems related to that proposed great project, this paper is especially welcome and valuable at this time. It is evident that the authors speak from a knowledge born of experience, from success and failure met within their own experience and remedial effort; one has here a summation of it all, concisely and briefly recorded. Mr. Aylett.

In the entire field of engineering activity and enterprise none invites such delay, difficulties, anxiety, expense, and danger as the work of tunnel building by the pneumatic shield-driven process. The deeds and heroism of soldiers and sailors have been lauded in verse and song since time immemorial. We would not take one leaf from the laurel crown the world places on the brow of the man who risks his life for his country. He is worthy of all the admiration a grateful people can give; but peace as well as war has its heroes. The world is comparatively ignorant of the deeds and dauntless spirit of that other army of intrepid fighters who go down into the bowels of the earth and under the waters thereof to battle for the progress of civilization and uplift of humanity in the face of dangers lurking everywhere.

The writer's experience with shield-driven tunnels and pneumatic work has brought him face to face with many of the difficulties enumerated by the authors. In his effort to forestall or remedy such difficulties, considerable thought and experimentation has been directed toward modifications of existing practice.

The great stiffening effect and rigidity afforded to sheet metal by corrugations is common knowledge. Such corrugations afford like effects whether the metal used is flat, circular, or in other shapes. In fact, the strength and rigidity of sheet metal is increased to such an extent by corrugations or ribs that to-day it is used for purposes for which the plain flat sheets are entirely inadequate. This result is obtained with no increase of sectional area of the metal itself. The corrugated sheet metal culvert is an example. The most recent type of the garbage pail—which even defies the tender mercies of the collector—is another. Observation and experiment have led the writer to believe that corrugations, or, more properly, fins or ribs may be applied to the exterior surface of tunnel linings with decided advantages. These fins or ribs should be applied longitudinally and circumferentially. Although it appears that the provision of such exterior fins, in conjunction with the usual interior flanges, would afford sufficient strength and rigidity to meet ordinary conditions, still, in extraordinary cases, in order to insure longitudinal continuity of the usual interior flanges, some modifications of them would be necessary.

* Hollis, N. Y.

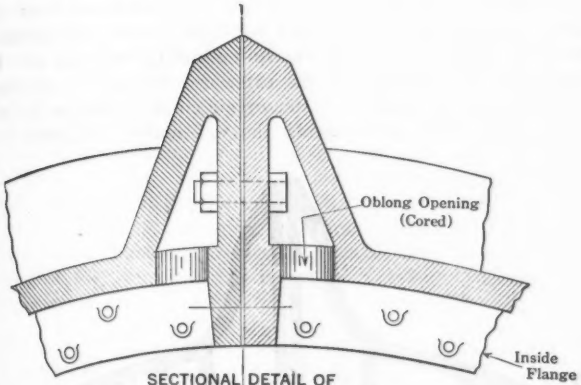
Mr. Aylett.

The addition of interior ribs suggested by the authors would be in this direction. The longitudinal ribs or fins proposed by the writer would protrude radially from the exterior surface of the lining and be located at regular intervals around its circumference in sets of four, eight, or more, as circumstances demand. (Fig. 19.) The width, area, section, and number of these exterior fins would depend on the tunnel diameter, character of soil penetrated, arrangement and power of rams, and air pressure. The same factors would influence the location and design of exterior circumferential flanges when such are required. It appears evident that such exterior protruding fins embedded in the surrounding material would exert a great stabilizing and stiffening effect on the lining, by virtue of their dual service as longitudinal stiffeners and soil anchors, while their location and design are such as to enable them to encounter and resist forces from any direction, whether from the inside or the outside.

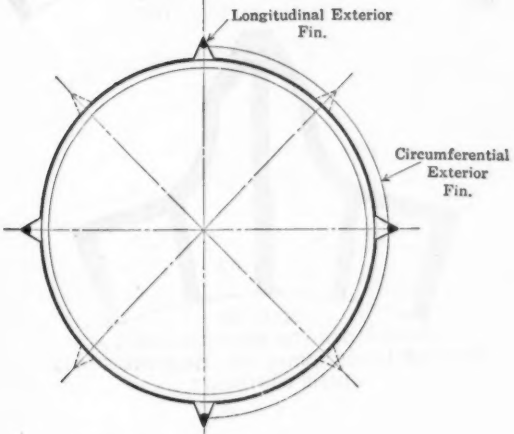
The function and location of such ribs applied to tunnel lining are somewhat analogous to that of bilge-keels on a ship. In effect, however, their range and influence would be greater. Thus, the top and bottom exterior longitudinal fins would resist horizontal pressures or displacements, the horizontal fins (and all others in the central horizontal third) would resist vertical pressures or movements, and the longitudinals would also resist ram pressures and air pressures.

Circumferential exterior ribs, however, by their location and soil anchorage, are especially adapted to resist ram and air pressures; in fact, their resistive action against interior air pressure is similar to that of hoops on a water tank or barrel. The use of inside ribs or tie-rods, etc., to resist air pressure in a tunnel is on a parallel with the use of inside hoops to resist hydraulic pressure in a tank or barrel. The action of air pressure in a cylindrical tunnel is identical with that of hydraulic pressure within a cylindrical tank, and the means used for controlling forces identical in action and effect should be similar. In this case the strategic point of control and attack against distortions and displacements is outside, not inside. Tie-rods and bracing can avail but little, and they are a great inconvenience. The admission of sufficient quantities of soil through the shield doors, as mentioned by the authors, is one means of outside control, in that it relieves outside pressures. Modification of existing practice, as suggested, is another means of outside control of both exterior and interior forces, and this concerns largely the proper design of a lining which will not only sustain permanent and temporary stresses, as the authors state, but also be capable of supplementing skin friction by direct soil support and resistance by anchorage therein, thus warding off and counteracting from the outside forces of distortion and displacement.

Mr. Aylett.



SECTIONAL DETAIL OF
LONGITUDINAL EXTERIOR FIN.

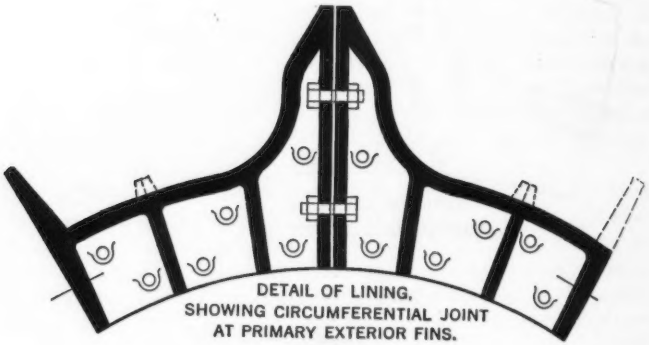


SECTION OF TUNNEL LINING,
SHOWING LOCATION OF EXTERIOR.
FINS.

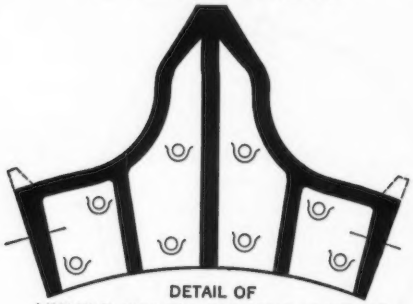
FIG. 19.

Mr. Aylett.

Another advantage afforded by such exterior protruding fins would be their action as cut-off walls for escaping air currents or water. Such currents travel along lines of least resistance, which are undoubtedly between the exterior surface of the lining and the adjacent soil. It is evident that the presence of the exterior longitudinal and circumferential fins in the paths of water or air currents tend to lead them outward, thus somewhat relieving the wet material adjacent to the



DETAIL OF LINING, SHOWING CIRCUMFERENTIAL JOINT AT PRIMARY EXTERIOR FINS.



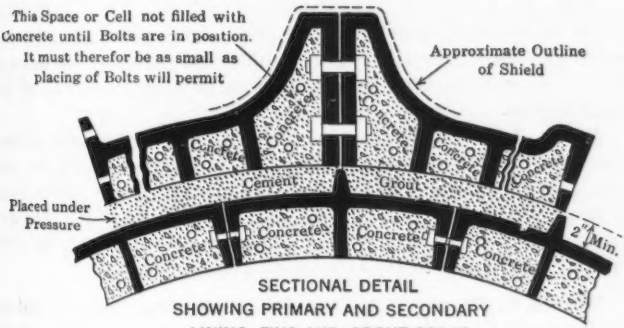
DETAIL OF LINING-BLOCK FOR BREAKING JOINTS AT EXTERIOR LONGITUDINAL FINS, THUS PRESERVING THEIR CONTINUITY.

FIG. 20.

skin from the usual agitation, churning action, etc., of air pressure through leaks. This action renders such material, a viscous lubricative fluid around the entire circumference. Thus, frictional resistance between the lining and its surrounding soil is maintained to a more or less extent by protruding fins, according to soil conditions, etc. The additional construction sectional area provided by the fins affords

ample abutment space for rams, and thus breakages of lining would be avoided. When necessary and desirable, rams of higher power may be located in line with the main longitudinal fins—and those of smaller capacity intermediate—thus proportioning the ram pressures to their respective supporting abutment areas, the ram stresses being transmitted and distributed to the lining through the longitudinal fins and directly to the soil by circumferential fins. Mr. Aylett.

There has been considerable professional discussion recently as to the merits of metal and concrete lining blocks. Strange to say, a composite block has not as yet been brought forward. The field appears to be both interesting and promising, and is worthy of thought and development. The ideal composite block, of course, would be one that embodied the good qualities of the combination of materials composing it. The blocks shown in Figs. 20 and 21 are designed with a



SECTIONAL DETAIL SHOWING PRIMARY AND SECONDARY LINING; FINS AND GROUT SPACE.

FIG. 21.

view to use either with or without concrete, as conditions may demand. The advantages of such a block are the greater additional strength and rigidity afforded by its primary and secondary exterior fins. Furthermore, the interior radial flanges and diaphragms divide its convex surface into rectangular voussoir-shaped spaces or cells, so that when filled with concrete the result is a concrete voussoir lining with perfect contact metal joints, the concrete thus performing a dual service as portion of block and as permanent tunnel lining.

The concrete may be placed before or after bringing the blocks into the tunnel. In order to avoid any form work or centering whatever for concrete, all blocks above the horizontal diameter, at least, should be filled prior to being placed in position. Those below may be filled after being placed, as the work proceeds, thus affording a good surface for construction operations. The lighter inner ring shown in Fig. 21

Mr. Aylett.

is intended for use with large diameters only or when soil conditions demand. Such a section would be absolutely water-tight and capable of holding its own in any emergency. In the entire double-ring section, Fig. 21, there are combined, three different linings adaptable to varying conditions and diameters, namely:

1.—A cast-iron or steel block lining provided with exterior longitudinal fins and interior voussoir cells. This section alone is suitable for severe conditions and large diameters.

2.—The same as No. 1, with concrete voussoir lining. This section affords permanent lining without centering.

3.—The same as No. 2, with a secondary composite ring and grout water-proofing cushion between. This cushion is placed under pressure in longitudinal cylindrical sections of the tunnel.

Thus, No. 1 alone, or its combinations with Nos. 2 and 3, provides a means of repeated, rapid shifting from one section to another, as unforeseen conditions may require, without loss of time, leaving a permanent concrete-lined tunnel, as the work proceeds, with any of these combinations.

Blocks of the general character shown may be of cast iron, or structural steel, and with some modification it is also possible to roll a suitable steel section of this general type and of cutting such a section to proper lengths. A pressed steel section is also possible. The grout space will permit of the use of a secondary lining of varying depths with no interference of the interior diameter or clearance.

Mr. Parmley.

WALTER C. PARMLEY,* M. AM. SOC. C. E.—This paper is valuable for the many facts of experience given and for the discussion of principles which are suggestive, although the speaker cannot always agree with the conclusions reached. The authors rightly utilize the Rankine formulas for earth pressures, but apparently fail to take into full account certain limitations or modifications which need to be made when applying them to actual practice. It must not be overlooked that the Rankine formulas are founded on one property of earth and one only—that of internal friction—and they ignore the universal fact that earth in its natural state is more or less compressible and has very material, and, in some cases, determinative, cohesive qualities. Where earth is disturbed during construction its original nature may be altered temporarily and even permanently, so that unequal settlements may take place, thus greatly modifying the direction and intensity of the thrusts. After readjustment it may become either more, or less, dense than it was in its original condition.

* New York City.

Mr. Parmley.

Therefore, the fundamental statement of the authors that

"The horizontal pressure on the tunnel is always at least equal to the active pressure, p_1, but if the condition of internal stresses in the tunnel lining should so require, a greater horizontal pressure will be developed of such magnitude as will be required to provide the necessary equilibrium, but under no circumstances greater than p_2"

the speaker believes to be incorrect.

The late Sir Benjamin Baker, Hon. M. Am. Soc. C. E., many years ago, recorded numerous experiments and citations showing that the active pressure p_1 was rarely equal to, and often less than, one-half the value given by the Rankine formula. The speaker has also made many observations of the pressure of coal, sand, earth sides of excavations as indicated by the deflections of the timbering and the behavior of retaining walls, and in nearly all cases the pressure was less than the value of p_1 given by Rankine. So pronounced and persistent were these facts that more than twenty years ago, when the speaker was designing the Walworth Run Sewer in Cleveland, the active horizontal pressures on the sides of the arches were fixed at one-half only of the value given by the formula and the stability of the arches was determined by this condition.

The second part of the authors' statement just quoted needs some interpretation. In order to establish equilibrium between the internal and the external work it is necessary for the arch to deflect. In deflecting, some parts of the arch will move outward against the earth and others will move inward, or retreat from the earth. It is obvious, therefore, that the abutment property of the earth can do no work in supporting the arch unless the arch tends to move outward against the earth.

In this outward movement the earth becomes more compressed, but compressibility or elasticity is a property which is excluded entirely from the formulas, and the conclusions, therefore, are affected by this limitation.

The outward reaction may be either less or greater than p_2 if the effects of cohesion and compressibility of the earth are taken into account. The amount of work which the earth can perform in giving support to the arch depends on the distance through which it can act, as determined by the actual displacements taking place at the several points along the contour of the arch. To illustrate: Consider a circular tunnel ring, having a radius of 100 units, in fairly uniform, though not hydrostatic, material; it will be deflected to an approximately elliptical form with the short axis vertical. The variations in the horizontal pressure due to increasing depth from top to bottom will not

Mr. Parmley.

be included. The pressures on both the upper and lower halves, therefore, are equal.

In Fig. 22, the full line represents the original circle. The broken line represents the tunnel after deformation has taken place. That is, the vertical radius has become less and the horizontal radius greater so that the deformed shape is that of an ellipse. As the two curves intersect at the 45° points, nearly, a glance at the diagram is sufficient to show that only the lateral quadrants, so far as abutment resistance is concerned, are effective in sustaining the tunnel from spreading, the movements of the upper and the lower quadrants being away from the earth instead of toward it.

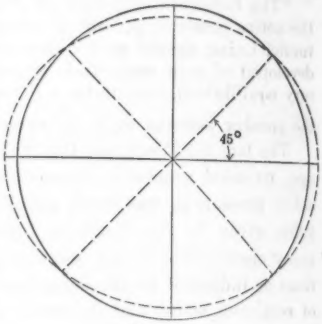


FIG. 22.

The effectiveness of the side resistance is plainly maximum opposite the center line where deformation is greatest, and decreases rapidly both above and below the center becoming nil at the 45° points. The rate in the decrease in effectiveness will be somewhat greater than is indicated by the decreasing deflections, because, unless loaded almost to its limit, equal increments in settlement in most earth imply increasing increments of loads as the earth becomes more heavily loaded and the ground becomes more compressed. However, on the basis of equality of increments of loads and displacements, the rates of change in effectiveness can readily be calculated.

The equation of the original circle is $x^2 + y^2 = 100^2$, and the equation of the ellipse having, say, a 1% change in the original length of the radius, is

$$\frac{x^2}{(101)^2} + \frac{y^2}{(99)^2} = 1.$$

The amounts of compression in the earth may be represented by the increases, Δx, in the values of x for any given value of y as the circle changes to the ellipse.

In Fig. 23 a portion of the side of the arch is shown with the displacements measured in a horizontal direction, the horizontal scale being magnified in order that they may be more easily observed.

The numerical amounts of these displacements for points up or down from the center, are shown in the diagram, being calculated for distances of 10, 20, 30, etc., up to 70, which latter point gives zero displacements at 45° from the center. If the width, 10, of each portion

Mr. Parmley.

shown, is multiplied by its average length between the two curves, that is, a mean value of the Δx, the area obtained will represent the proportion to the whole reaction which each 10-unit vertical height of the ring will be able to sustain. Each of the several percentages is indicated on its appropriate space, the total for each horn-like area above or below the center being, of course, 100, while the actual area is 50.

Within the range of deflections likely to be experienced in an actual case, the percentages for each portion of the whole thrust cut off by the horizontal lines would remain practically constant whether the actual deflection amounted to more or less than the 1% assumed in determining the foregoing figures.

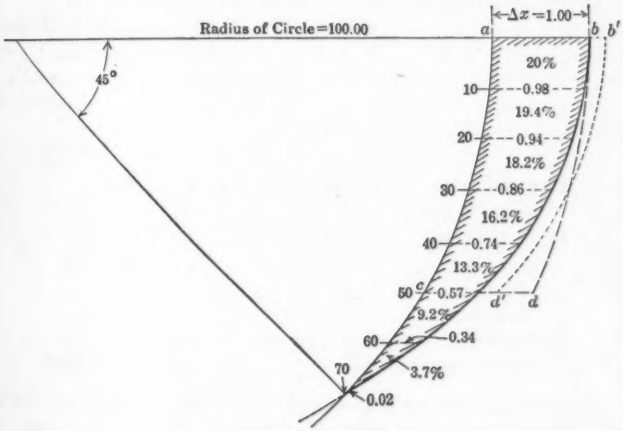

FIG. 23.

If the total effects for each belt of width 10 be added, from the center up to 50, or one-half the radius, it will amount to 87% of the total effect on the full 45° arc. As the 45° point is approached, the horizontal displacements become so small that it is doubtful whether much reliance can be placed in them, since appreciable compression nearly always takes place before the supporting power of the earth is developed to a useful extent. It seems reasonable, therefore, to ignore all horizontal abutment effects beyond one-half the radius either way from the center. This condition requires that the 13% be distributed over the remaining area, or averaged, so that the total area shall remain unchanged. If the pressure is regarded as constant for the remaining width over which it is applied, its intensity will be equal to the maximum at the center. The total reaction then may be shown by the area, *a-b-c-d*.

Mr. Parmley.

It is likely, however, that in fact the actual pressure will not be constant, because the varying amounts of deformation will develop varying amounts of compression. It is perhaps more nearly correct, therefore, to consider that the 13% of the total pressures lying below and above points one-half the radius from the center is distributed over the middle belt uniformly, in which case the total resistance of the abutment would be represented by the area, a-b'-c-d'. In this case, the belt of uniform width, b-$b' = 0.14$, is added to the area remaining after cutting off the tip of the horn below Point 50.

If the ground is hard enough to sustain an abutment load represented by this area, the ring will be sustained with only a small amount of deflection, but if not, serious spreading will take place.

A very useful set of results has been calculated by Mr. B. Haukelid* and from these formulas the following reactions are tabulated, giving the intensity of the reactions at the abutment when spread over various vertical widths, in which p represents the intensity of the pressure and r the radius of the circle:

	Intensity of pressure.
If reaction is concentrated into one horizontal force applied at the center.....	$1.12\,pr.$
If distributed uniformly over one-fourth the diameter	$2.42\,p$
If distributed uniformly over one-half the diameter	$1.31\,p$
If distributed uniformly over the side quadrant.	$1.10\,p$
If distributed uniformly over the full diameter.	$1.00\,p$

The necessary lateral support in terms of the vertical unit of loading thus becomes known for the various depths of abutment shown. As the vertical loads per square foot are usually determined with a measurable degree of confidence, if for a given kind of ground the reaction as shown does not exceed the abutment strength of the ground, the structure will stand.

In order to bring into sharper relief the relationship between vertical pressures and lateral stability needed for different modes of its application, several curves are shown in Fig. 24. The angles of repose are given as abscissas, and the intensity of horizontal pressures and resistances as ordinates, Ordinate 1 being that which represents the intensity of the vertical pressure, p. Utilizing the Rankine formulas for the present, Curve No. 1 shows for any declivity of repose the active horizontal pressure, being the locus of the expression, $\frac{1 - \sin.\ \phi}{1 + \sin.\ \phi}$.

* *Engineering Record*, June 14th, 1913.

Mr. Parmley.

FIG. 24.

Mr. Parmley.

For a vertical cliff, $\phi = 90°$, the pressure is zero, and as the angle decreases the pressures increase until for fluid or hydrostatic case the pressure equals the vertical pressure. Ordinate 1, therefore, is an asymptote to the curve.

By comparisons with the intensities required as given previously, it is at once obvious that the active pressures cannot sustain the outward thrusts from the vertical pressures except for the hydrostatic case. For all others there still remains a lateral thrust which must be absorbed through internal stiffness of the structure, or by the resistance of the earth.

In the diagram, Fig. 24, Curve No. 2 is the locus of Rankine's equation for maximum horizontal stability, $\frac{1 + \sin. \phi}{1 - \sin. \phi}$. Theoretically, for a vertical cliff, the resistance would be infinite, but the resistance rapidly drops away as the angle of repose becomes less and less and the curve finally meets Ordinate $1 = p$, for the hydrostatic condition. If full reliance could be placed on this curve, representing the stability of the actual earth, the ring would be safe even for quite fluid conditions of the ground, providing the structure could be built in intimate contact with the earth. As already stated, however, the fact that the ground must be compressed by an appreciable amount before useful resistance is developed, to rely on the support indicated by Curve No. 2 would be hazardous. The speaker has never felt that he could rely on more than about one-half the values represented by Curve No. 2 and believes that ordinarily it is not wise to go beyond this limit.

Curve No. 3 shows resistances, therefore, of one-half the values given by Curve No. 2. Comparisons of the values given by this curve with the intensities for the various widths of abutment show that the ring would be sustained for a 1 on 2 material if firm contact at the sides extends along a width of at least one-half of the diameter; but that for any softer material the deficiency must be taken up in the internal stresses in the ring. Conclusions, however, must be drawn from such charts cautiously and by the exercise of a great deal of judgment. Cohesion tends to increase the lateral stability, but, on the other hand, materials with a high degree of cohesion are likely to require more compression in order to develop their resisting qualities and so tend to neutralize the beneficial effect of cohesion.

Because of these reasons and the fact that cohesion when present operates to prevent the development of the active pressures, it is not believed that in any but exceptional cases can active horizontal pressures have much effect on the top and the bottom quadrants, and that reliance must be placed chiefly in the resistance against the side quadrants to prevent spreading. The case of ideal active pressures discussed by the authors is interesting and instructive as illustrating

the operation of certain laws, but cannot be applied directly to practice without considerable modification. Mr. Parmley

The speaker agrees with the authors that in a tunnel lined first with cast-iron or concrete segments that the primary lining should be strong enough to withstand all the bending moments caused by construction operations without dependence on further support, not only for the reasons which they give, but because of the practical impossibility of determining just what the ultimate pressures of the earth will be and the lack of constancy of these pressures, due to the changing character of ground penetrated. To feel safe, the engineer should make the structure capable of meeting a greater range of conditions than he believes will actually have to be met.

With the opinion of the authors regarding the suitability of precast concrete blocks for tunnel linings, the speaker does not find himself in agreement. In fact, some of the statements made seem little short of absurd to any one having experience in this kind of construction. The practicability of blocks is not limited to dry soil and favorable conditions, as is abundantly proved by existing important sewers and tunnels built in most difficult situations. Instead of being less able to withstand bending stresses than cast-iron segments, as stated by the authors, the contrary is the fact, as can easily be shown. Thus, assume that the tangential component of the thrust at any given joint cuts that joint at the limit of the middle third, there is then a state of no pressure at one edge and double the average pressure at the opposite edge of the joint. Any further eccentricity of load will produce tension in the ring, and a consequent tendency for the joint to rotate on itself. Take, for example, a cast-iron lined tunnel as now proposed for the vehicular tunnel under the Hudson River. This ring is 14 in. in depth from the outside of the iron to the inside of the stiffening flanges. If the tangential thrust at a given joint, say, at the springing line, is 100 000 lb., which is about what it will be, and if the thrust cuts the joint at a distance of one-sixth of 14 in., or $2\frac{1}{3}$ in. from the center line, the ring will be on the point of rotation or a state of tension at the radial joint. The bending moment, therefore, at the point where actual tension and rotation begins is 100 000 times $2\frac{1}{3}$ in., or 233 000 in-lb. Actually, the moment is less than this because, for simplicity of illustration, the center of the joint is taken as 7 in. from the outside instead of only $4\frac{3}{4}$ in. from the outside to the center of gravity of the section.

A concrete block ring to meet the same situation would be about 33 in. in thickness. If a 100 000-lb. thrust be applied at the limit of the middle third, it will produce a moment of 100 000 times one-sixth of 33 in., or 550 000 in-lb., or about two and one-half times the capacity of the cast-iron joint before tension begins. Nor should it be for-

Mr. Parmley.

gotten that concrete block construction lends itself to reinforcement and that, contrary to the alleged relative weakness of the concrete block structure at the joints, it can be reinforced with steel bars embedded in grooves and grouted in as the rings are erected, thus making the concrete of vastly greater strength.

Contrary to the views of the authors, also, the speaker regards the advantages almost wholly on the side of concrete blocks. Should settlement or distortions cause any cracking or opening of the joints, penetration of the water will do no harm to the structure itself, as the cement grout or mortar of the joint is not affected. On the other hand, should there be any leakage of a finished joint between the cast-iron segments, the bolts of the joints will come into contact with the water and ultimately become weakened by rusting.

The authors apparently fear that blocks of a concrete ring would be liable to displacement because of the small arc of the circle which they might occupy, and their methods of overcoming these imaginary displacements are so fanciful as to suggest that they have not made sufficient study either of the geometry or mechanics of the matter or speak without any basis of experience in this type of construction. Nor need the matter of water-proofing cause worry, as will be appreciated by engineers of experience in this class of work. The fact that many hundred thousand and even millions of dollars worth of work, under all sorts of conditions and difficulties, have been built successfully is sufficient refutation of the specious argument that concrete block construction is not suitable for subaqueous tunnels.

As the proposed vehicular tunnel under the Hudson River is particularly in the minds of engineers in the vicinity of New York City at the present time, and as it leads up to seemingly unnoticed possibilities in the large double-deck roadway tunnel, a property of arches which seems to have been overlooked by engineers, will now be referred to, as no mention of it has been made in the discussions up to the present time.

In Fig. 25, let the horizontal line, *A-X*, represent an axis of abscissas and *A-Y* an axis of ordinates. The points marked 10°, 20°, etc., represent points along a circular arch, 10°, 20°, etc., from the top, and include points down to the springing line at 90 degrees. Bending moments in the arch are plotted upward for positive moments (those producing tension in the inside of the ring) and negative moments are plotted downward, *A-X* being the axis of zero moment.

The curve, *BCD*, represents the moments for a circular ring supporting and sustaining uniformly distributed vertical loads, the moment at 0° being $0.25\ pr^2$, where p is the load per square foot and r is the radius of the circle. At 90°, the moment is the same, but with the negative sign, the point of zero moment being at the 45° point.

Mr. Parmley.

The moments for the lower half of the ring will be a repetition of those shown, counting the 0° at the bottom.

If there is a lateral pressure uniformly applied from top to bottom, its effect will be to shorten the several ordinates in the same proportion

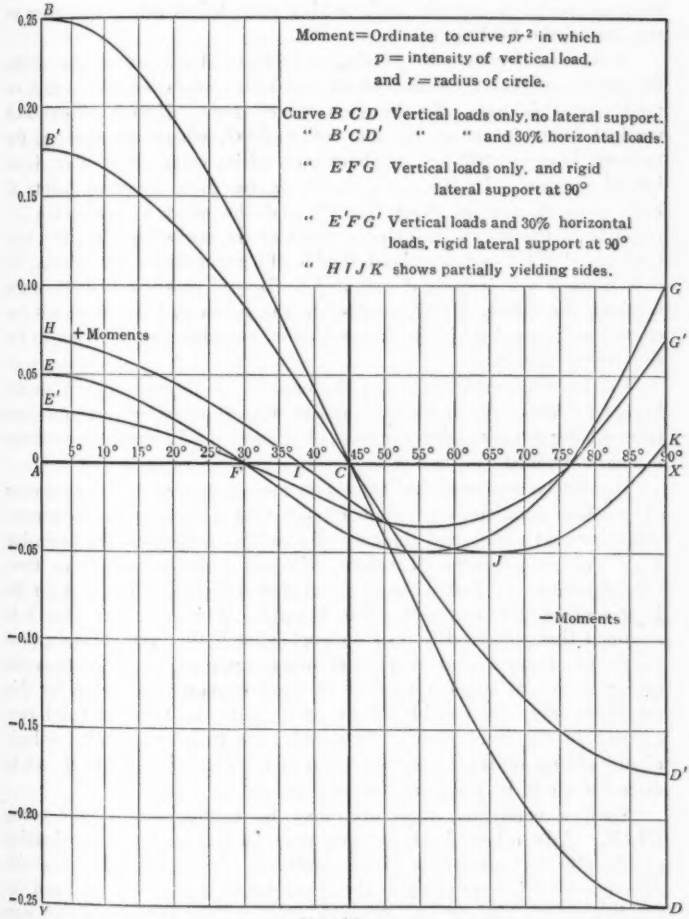

FIG. 25.

as that which it bears to the intensity of the vertical load. The curve, *B'CD'*, represents the case where the lateral pressure intensity is uniform and equal to three-tenths of the vertical intensity. As the

Mr. Parmley

lateral pressures approach the vertical in intensity, the curve of moments approaches the axis, *A-X*, or zero moment, thus producing tangential thrusts only in the ring. Curves *BCD* and *B'CD'* and similar ones are applicable to arches and rings having no lateral abutment supports, so that the arch or ring may deflect freely according to the law of the loading.

Now, consider the case of absolutely rigid abutment support at the 90° point, so that there can be no spreading whatever of the arch or ring. In this case, the moment curve for uniformly distributed vertical loads is shown by the curve, *EFG*, where, at the top, the moment is only 0.049 pr^2, or about 20% of its value where there is no lateral support. In this case, furthermore, there are two points of zero moment, one at about the 30° and the other at about the 75° point from the crown, and the moment at the springing line, 90°, now becomes $+ 0.101\ pr^2$, or about double the moment at the crown. In case there is a uniformly distributed horizontal pressure of 30% of the vertical, the curve, *E'FG'*, represents the moments; the moments for corresponding points in the lower half of the ring are the same as for the points shown.

In the same manner as for the case of no lateral support, as the horizontal pressures approach equality with the vertical pressures, the moment curve approaches the axis, *A-X*, and the hydrostatic condition is again reached.

It must be admitted that these two cases represent the two extremes of possible conditions of support, the first representing no support whatever and the second the case of absolute support at the springing line. All actual cases, therefore, will fall somewhere between these two extremes, and just where a given case will fall is a matter for the judgment of the engineer. For example, if in a given case it is assumed that the condition of support is such that the springing line yields an amount that represents one-quarter of the way from the condition of no support to that of fixed support, the curve for this condition may be considered at each point to have traveled one-quarter of the total journey it would have to go to reach the limit of unyielding support, since the ratio of the rate of travel to the whole distance would be the same for each point.

Such a condition, therefore, may be represented by the curve, *HIJK*. Any other similar curve may be drawn by approximation graphically to represent a given condition of support. The unavoidable errors of judgment as to the character of a given ground and the rigidity of the support are so much greater than the errors that may result from imperfections in the curves that practicable accuracy is attained for any desired condition.

Now, a fundamental law of physics is that for equal pressure in all directions there must be no internal friction, that is, the material must

be a perfect fluid. Conversely, if the material is not fluid there is internal friction and there is an inequality between the vertical and the horizontal components of the weight. Where there is internal friction the passive lateral resistance must be greater than the active horizontal pressure. Rarely is it possible in actual practice to have a case that does not fall somewhere in the intermediate and somewhat indefinite zone between the extreme curves of Fig. 25. Mr. Parmley.

In the recent discussions of the Hudson River Tunnel, these facts, shown in Fig. 25, appear to have been entirely overlooked when considering the nature of the ground that will be penetrated and the means necessary to be used in order to resist the varying pressures that will be encountered.

If a tunnel is adopted, however, which is large enough to accommodate two levels of roadway, one above the other, it becomes possible to realize the extreme limit where fixed supports at the sides are afforded. A horizontal tie or strut can be built into the tunnel construction as it is erected, extending across the horizontal diameter of the tunnel, which will absolutely fix the span of the arch and thus enormously reduce the bending moments, as shown by the curves of Fig. 25.

The lower half of the tunnel becomes an inverted fixed 180° arch, the exact counterpart to the upper half, except for the somewhat increased horizontal pressures due to the greater depth; but the increased depth will not seriously alter the condition of fixed vertical tangents at the ends of the horizontal diameter or of fixed horizontal tangents at the top and the bottom of the tunnel. They will remain nearly constant during all the variations of loading conditions, and this, together with a constant span of arch, produces the condition necessary for fixed 180° arches.

Means for fixing the horizontal diameter of the tunnel can readily become part of the permanent roadway construction for the upper level and, therefore, would not be visible in the finished work. Fig. 26 shows the cross-section of such a possible structure. The internal diameter shown is 38 ft., and the thickness of the wall is 42 in. Without going into detail, the stresses and thrusts in this ring are less than they are for a tunnel having an internal diameter of only 25 ft. and a thickness of 33 in., and they are less than in the proposed cast-iron lined tunnel with an exterior diameter of 29 ft. Furthermore, this ring, with the length of the horizontal diameter fixed, will sustain loads for the entire range of conditions from a material that stands on a natural slope of 1 vertical to 3 horizontal, and the horizontal pressures equal only 52% of the vertical, through the whole range of unstable materials even to the hydrostatic condition, without theoretically even requiring reinforcement. In order to withstand this range of possible conditions,

Mr. Parmley.

a full ring of the same size unsupported at the center by interior construction requires a thickness of 48 in. of concrete heavily reinforced.

Other features which are believed to be important in this plan, but which will be only touched on, are the cores which are designed to slide within the blocks to take the reactions from the jacks and so relieve the blocks from all breaking or shearing strains or possible displacements when the longitudinal joints are staggered. This matter was discussed* at the meeting of the Society on March 19th, 1919. The cores, as shown, consist of high-grade, hooped concrete containing sections of steel I-beams at the center. Cores thus designed of 11 in. in diameter are easily capable of taking the entire thrust of 72 jacks of 200 tons each, the amount of power required to drive a shield of this size, if it is equipped with relatively as much power as has been used in other tunnels built under the Hudson River. If made to meet near the centers of the block-rings, the cores may be utilized later to tie the rings together longitudinally, and when the rings are fully grouted, will give great longitudinal strength to the tunnel.

The great advantage in a tunnel of sufficient size to permit three trucks abreast simultaneously in each direction, over that to be gained by the two-line tunnels now contemplated, should justify further careful consideration of the construction of a tunnel of this type.

For a tunnel of large diameter, the possibilities of a structural steel concrete lined tunnel, as indicated by the authors, might well be investigated. The life of the structural members could hardly be expected to equal that of cast iron or concrete, because either Bessemer or open-hearth steel suffers much more rapid corrosion than cast iron, and the concrete suffers none at all.

There is a great disadvantage, however, in any plan requiring a composite ring, such as cast iron or structural steel with concrete lining. Either the ultimate strength of the tunnel will reside exclusively in the strength of the iron ring, the strength of the concrete ring, or in the combined strength of the two materials when acting in the ratio of their respective moduli of elasticity. Figured in this way the composite section cannot be permitted to sustain tension at any point greater than the accepted standards for concrete, unless it is still further reinforced with steel bars. If the ring, on the other hand, is figured as a cast-iron ring acting alone, although of less effective thickness, the fact that the iron, whether wrought or cast, may safely withstand many times the tensile stress permissible in the concrete, results in giving a greater effective strength than is obtained when the two dissimilar materials are figured together. The concrete, unless built very heavy, will add practically nothing to the strength of the

Mr. Parmley.

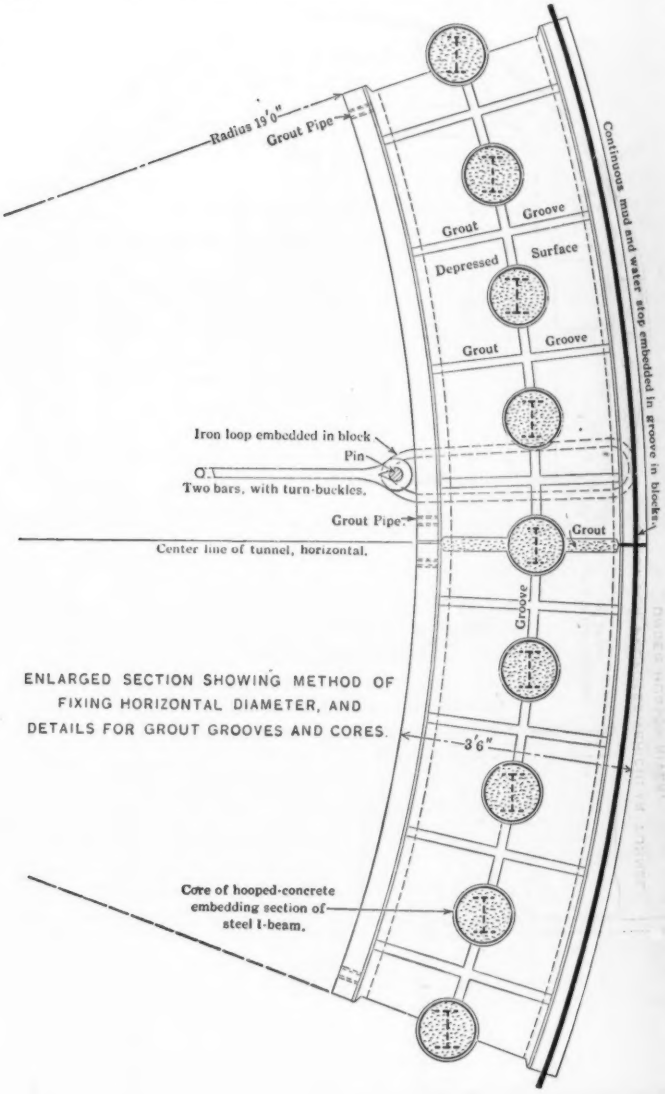

FIG. 27.

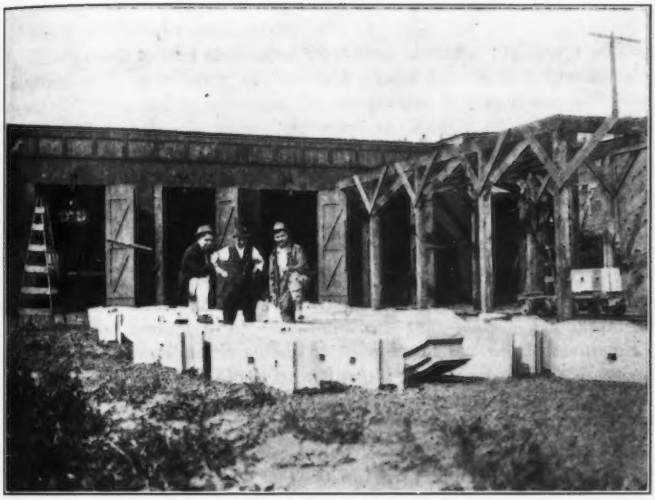

FIG. 28.—PRECAST CONCRETE BLOCKS FOR TUNNEL WORK.

FIG. 29.—INTERIOR VIEW, CLEVELAND WATER SUPPLY TUNNEL.

tunnel beyond greater stability due to the added weight. This fact can be easily verified by calculation. Mr. Parmley.

In contrast to this structural weakness, if either plain or reinforced concrete rings consisting of concrete blocks are used, a homogeneous section of material is obtained, the properties of which are well established. The strength, therefore, may be readily calculated and the results given full confidence.

The concrete blocks being only a substantial fraction of the cost of the cast-iron segment throws the balance of advantages clearly on the side of the concrete structure.

Some have feared that concrete may become disintegrated by the waters under the Hudson River, but past experience in the waters around New York City and vicinity give no proof that any such corrosion of precast concrete blocks would ever take place. The claim does not appear to have merit sufficient to warrant extended discussion.

Any claim that the block tunnel could not be erected, or, if erected, would fall to pieces as it is composed of so-called loose blocks (such claims have actually been made) is too childish to merit serious answer. Fig. 28 shows some of these so-called loose blocks for an actual tunnel (representing more than $1 000 000 worth of them), with the construction of which the speaker was intimately connected. They were erected and they have not yet fallen apart, although the tunnel is deeper below the water surface and much of it is in worse material than will be encountered under the Hudson River. The speaker refers to the intake tunnel under Lake Erie at Cleveland, Ohio. Fig. 29 shows the completed tunnel, which is a standing monument, and will stand for ages, to confute the "doubting Thomases" who are now endeavoring to convince the public that cast-iron segments are the only possible or safe lining for the proposed vehicular tunnel under the Hudson River.

The authors have indeed performed a useful service in giving the Society a paper of such thought-provoking character.

The speaker is glad indeed that Mr. Holland makes a statement as to his open-mindedness toward tunnels of various types of construction, because that open-mindedness will tend to help the construction, whatever type it may be. In regard to the bending moment stresses in the rings, whether they are of cast iron or concrete makes no difference. Mr. Holland's statement assumes that in soft ground there would always be much greater bending stress than in harder, dryer material. The facts are much to the contrary. There is likely to be a much greater bending stress in a structure at the bottom of a ditch than when it is put in a tunnel heading. The heaviest stresses come often at the bottom of a deep ditch, where the material has been disturbed, and where it can have its full effect on the ring; so far as the speaker's analyses have gone—and he has considered various condi-

Mr. Parmley.

tions under the Hudson River as applied to these propositions—as the more liquid conditions are approached the bending stresses decrease, while the thrust increases. The thrust causes no trouble, if it can be kept near the center of the ring. It is the bending stresses that cause trouble.

Mr. Holland apparently omitted to note that the concrete blocks are perfectly capable of being reinforced, and in a great amount of work there has been provided solid steel connection between the joints, which he seems to want. That is what the speaker advocates in every case where the transverse bending moments seem to demand it.

As to the question of water leaking in, the study suggested by Figs. 26 and 27 contains many details which were not indicated. It can be shown that by means of an asphalt strip, water pressure can be held back until the ring can be grouted from the inside.

Even without this provision, of the speaker's knowledge it has been found that at 120 ft. below the level of hydrostatic pressure, where the tunnel was in mud, it has been possible to make it tight, whether the air pressure was on or not. The tunnel referred to was 10 ft. in interior diameter; but the mud will come through a ¼-in. crack just the same whether the tunnel is 10 ft. or 100 ft. in diameter.

In Fig. 29, showing concrete block construction in this tunnel, long irregular shadows appear, due to the fact that an irregularity amounting to only ¼ in. throws a shadow 1 in. or more long, and gives an erroneous impression. Indeed, this concrete tunnel has a splendid interior surface, as far as regularity goes.

In regard to shearing stresses from the jacks, Mr. Holland is entirely right, and it is to overcome them that the speaker suggests using the cores, as shown in Figs. 26 and 27, placed so that they will not be rigidly bound in the blocks, thus relieving them of the shearing stresses, which it is practically impossible to do with cast-iron segments.

Mr. Holland.

C. M. HOLLAND,* M. AM. SOC. C. E.—In describing the behavior of tunnel lining during construction, the authors refer to the movement of the Pennsylvania Railroad Tunnels under the North River and the settlement of an East River Tunnel, which the speaker presumes is the Battery Tunnel, although it is not mentioned by name. The speaker believes that the authors do not intend to convey the impression that the deviation from theoretical line and grade was due wholly to weaknesses in the tunnel lining. These deviations were due principally to lack of control of the tunnel shield.

It is stated in the paper that the shortening of the vertical diameter and the lengthening of the horizontal diameter, which is the second and last change in shape of section which the cast-iron lining under-

* New York City.

Mr. Holland.

goes in Hudson River silt, was continuous in the Pennsylvania Tunnels until the secondary lining was placed. The speaker does not understand this to be true from the reports of that work. If this condition was true, it might indicate a much more serious stress in the lining, particularly after distortion had reached certain limits. Of course, this distortion could be taken care of by interior reinforcement which would reduce the elastic deformation of the ring. In any event, there would be, under heavy loading, a considerable elastic deformation in the circular ring similar to that which would occur in any structural member under bending, and the larger the diameter the greater would be the elastic deformation without actually approaching the point of failure.

The stresses in a tunnel lining under construction vary greatly with respect to the care taken both in operating the shield and assembling the segments:

1.—Thrust of jacks depends on method of excavating face.
2.—Shearing and bending stresses are often excessive, due to:
  (*a*) Variation in size of segments, causing lips on the circumferential joint.
  (*b*) Variation from circular form, often causing open horizontal joints.
  (*c*) Face of ring not a true plane, causing lips in circumferential joint.
  (*d*) Foreign material between segments.
3.—Binding of the tail on the exterior lining causes heavy, unbalanced loads.

All these matters are of the greatest importance, and, unless careful attention is given to them, will result in stresses far in excess of those due to earth pressure after the lining has left the shield. Most of the cracked plates are broken inside the tail of the shield for the reasons just stated.

The curves of progress given in the paper are of interest, but it appears to the speaker that to a certain degree they may possibly give undue weight to the progress of small tunnels. There is no question but that the progress as shown has actually been attained, but it does not follow necessarily that greatly increased progress cannot be made in tunnels of larger diameter with the present increased experience in tunnel driving. Tunnels recently constructed have been of the smaller type and, consequently, the benefit of experience gained in other tunnels has been of the greatest help and has made possible faster rates of progress.

There is a limit to the size of tunnel which can be driven at all, in that the diameter of the shield affects the amount of cover required overhead. In connection with the driving of the East River Tunnels

Mr. Holland.

of recent date, the rule generally followed was to have a cover one and one-half times that of the diameter of the tunnel whenever the water pressure was balanced at the bottom of the tunnel. This was a ratio worked out from computations based on the weight of the material forming the bed of the river, and it will vary with the character of the material through which tunnels are being driven.

In regard to the caulking of cast iron, it is stated that in order to be effective it must be done under air pressure, and when deformation takes place on the removal of the air, the caulking will be disturbed. The use of rust-joint caulking makes it necessary to caulk in compressed air, but, in recent years, this has been displaced by the use of lead which is always made tight when the tunnel is under normal air just before placing the interior lining of concrete. It would not seem that the movement of these tunnels, effected by tidal changes, would be sufficient to cause leakage, for, from the information in regard to the leakage of tunnels, it appears that, in terms of area exposed to seepage, the North River Pennsylvania Tunnel is one of the dryest tunnels in the vicinity.

In regard to the permanency of steel lining when exposed to salt-water action, there is some question. Reference is made to the shield erected in 1890, abandoned in 1891, re-excavated in 1902 after a lapse of eleven years, and used to complete one tube under the Hudson River. This shield was buried in the mud where there was little, if any, flow of water-bearing fresh acids or rust-producing chemicals continually to the structure itself. However, as the Hudson River silt is practically water-tight, a section of the tunnel in this material, if made tight, might be in very little danger of rusting. In the sand and gravel sections the conditions are plainly different. Articles of wrought iron and steel found during the excavation of the East River Tunnels in the shore sections show marked decomposition. A chain was badly rusted; a hatchet was so disintegrated that it simply furnished the outline of the original tool; an anchor and a small piece of chain showed definite marks of corrosion. It may be well to note in this connection that the prevailing idea is that the flow of ground-water toward the sea keeps the earth saturated in the vicinity of the shore with fresh water, such as is found when wells are sunk along the shore of the ocean. It was found in reading ground-water elevations in Clark Street, Brooklyn, that this elevation was approximately that of mean low water of the East River. This seemed to be out of the ordinary, and an effort was made to find its cause. It was learned that hotels and office buildings were pumping large quantities of ground-water from wells on the premises. This section, being almost wholly covered by pavement and buildings, only a small percentage of the rainfall percolated into the ground. Consequently, these wells were drawing

Mr. Holland.

so much water that the flow was from the East River rather than toward it, and the water pumped was slightly brackish. Shaft caissons with a steel lining have been sunk for tunnel work, but it is believed that in computing the strength of such caissons finally in place that full value should not be allowed for all the metal used.

Design.—In regard to the stress diagrams shown in the paper, and from which certain conclusions are reached, it does not appear that, with the loading symmetrical about the vertical axis, the line of pressure should cross the vertical axis at one point only. The speaker has not made any analysis covering the specific cases mentioned, but it appears to him that, under the condition of symmetrical loading about the vertical axis, the line of pressure should intersect the neutral axis at two points.

The eccentricity of the circumferential force in the lining for tunnels, the diameters of which vary from 12 to 36 ft., is stated empirically by the authors to be:

$$e = \frac{d^2 \sqrt{d}}{480}$$

The application of this formula to tunnels which have been analyzed by the speaker's engineering staff for specific loadings, varying somewhat from those stated in the paper, gives an eccentricity for a 29-ft. tunnel of 9½ in., while the analyses give an eccentricity of 2 in., and for a 42-ft. tunnel, the formula gives 23 in., while the analyses give 3 in. This discrepancy may be accounted for somewhat by the difference in loading, and also the fact that, in the analyses, 3° was assumed to be the angle of repose, but it does not appear that this discrepancy can be explained entirely by this variation.

The analyses which have been made in connection with the 29-ft. tunnel which has been recommended to the Bridge and Tunnel Commissions, under conditions of loading very similar to those used by the authors, indicate that the reactive pressures in the surrounding ground become effective when the angle of repose exceeds 2° 20′; whereas, the authors find that a 30-ft. tunnel under the assumed conditions cannot develop the reactive pressures until the angle of repose exceeds 22 degrees.

The speaker emphatically protests against the statement by Mr. Parmley that the New York and New Jersey Bridge and Tunnel Commissions have only under consideration twin cast-iron tubes. The Commissions and their engineers have stated repeatedly that they are open-minded on this question and in their report to the Legislatures of their respective States, they have shown alternative types of construction, using either monolithic concrete or structural steel with an inner lining of concrete and a protective covering of concrete on the outside. Further, the steel lining as discussed by the authors is now

Mr. Holland.

under consideration as well as other types of construction. The preliminary report of the Commissions as to cost was based on twin cast-iron tubes as it was considered that, with the limited time for study, it was the only method of construction which could be definitely recommended. The responsibility for the successful completion of this work rests on the engineers advising the Commissions, and they are in a position very similar to that of trustees in the administration of a trust fund. No trustee would be permitted to make any other than sound, conservative investments with funds under his charge and, similarly, no engineer in spending public funds should proceed with a method of construction which is not absolutely certain of success unless the saving which can be effected would make such a risk justifiable. None of the methods of construction thus far studied has warranted the elimination from consideration of twin cast-iron tubes which have as a precedent the twenty-two tubes already constructed and now in use under the East and Hudson Rivers.

The speaker has never questioned the durability of well placed concrete when built in a monolithic structure. One of his objections to the concrete block tunnel is the thousands of feet of joints which are introduced between the blocks, each of which is liable to leakage. Every engineer who has had to do with the building of concrete structures, particularly in tunnel work, appreciates the difficulty of getting a water-tight joint between two concrete surfaces.

Referring to the stress analyses on which some engineers place so much reliance, and the very complete demonstration submitted by Mr. Parmley, the speaker wishes to warn against the conclusions derived from such a source in that the complicated equations may be mathematically correct but their value depends on the assumptions. Frankly, the speaker considers Mr. Parmley's analytical discussion to be excellent mental gymnastics, dangerous in the extreme if the conclusions are applied to a shield-driven tunnel as the criterion of its adequacy. The speaker does not mean by the preceding wholly to condemn the application of structural mechanics to a tunnel lining for he has made similar analyses of tunnel rings, but they have been used only as one step in their design.

In the design of a tunnel lining to be built by the shield method under the Hudson River, it should be recognized fully that there are other materials which are to be encountered besides Hudson River silt, such as rock, sand, gravel, boulders, etc. All these materials are met with, and the lining must be capable of withstanding the worst set of conditions which can be brought to bear on it, so that a discussion as to whether or not there is cohesion in the Hudson River silt or as to whether Rankine's theory of earth pressures should or should not be applied, is not the real point at issue. In the speaker's

opinion, it is very largely a matter of the application of common sense based on experience, with such theory as is necessary to obtain a rational design. Mr. Holland.

In an old tunnel drift (Fig. 17), that was encountered during the construction of the Borough Hall Station, Brooklyn, N. Y., on the Clark Street Tunnel line, the material varied from fine sand to a coarse sand with gravel and in places there was sufficient cementing material to make it stiff so that it could be dislodged with difficulty under the blow of a pick. This latter condition is that of the material directly over the cap. In this earth, there is a considerable vibration from overhead traffic yet the load on the cap is only a very small portion of the total dead weight. There is a great lack of uniformity in materials and due to this variation serious conditions of unbalanced pressures are certain to arise. In his discussion of this paper, Mr. Parmley has dwelt with considerable emphasis on stresses in the tunnel lining as determined by earth pressures.

The timbering set, as shown in Fig. 17, is a very simple structure, yet the conditions which such a timbering set must meet in tunneling, are very indeterminate. In the construction of the Clark and Montague Street Stations in the tunnel under Brooklyn Heights, it was of the utmost importance to prevent any settlement of the ground, and every effort was made in timbering to wedge it so tightly that it would meet the ground rather than let the ground come down upon the timbering. The sizes and spacing of caps were computed approximately but, in some cases, it was found that intermediate caps were required. In certain places, the ground was unusually heavy due to the presence of water or to the fineness of the sand and the absence of all cementing material. The timbering was maintained successfully for more than a year without any serious disturbance to the buildings due to the fact that levels were taken on the caps and when movement was shown, all wedging which, by the way, was done by steel wedging between steel plates, was tightened and, if necessary, additional bents were inserted.

The study of the behavior of a tunnel lining under an assumed loading is of considerable value, but tunnel engineering is not a science in which the tunnel engineer deals with determinate loads such as is the case with the bridge engineer. It has been the speaker's experience that any tunnel strong enough to be built behind a shield has proved strong enough thereafter. The old Rapid Transit Tunnel from the Battery, in New York City, to Joralemon Street, in Brooklyn, N. Y., is a good example of a tunnel lining which was badly crippled during construction and yet has proved a sound structure ever since its completion.

Mr. Thomson

T. KENNARD THOMSON,* M. AM. SOC. C. E.—The authors are to be congratulated on the valuable and interesting paper they have presented to the Society. In regard to the hydrostatic pressure at the bottom, the speaker thinks that in all caisson and tunnel work it has been found that the air pressure required has been almost exactly equivalent to the hydrostatic head. If the hydrostatic head was increased by the weight of the silt, which is given as from 104 to 110 lb. per cu. ft., there would be an air pressure of from 75 to 80 lb. in these tunnels, which of course would be prohibitive. This question has arisen frequently in designing retaining walls for deep cellars in New York City. Some engineers claim that the pressures are increased by the weight of the sand and material, while others go to the opposite extreme and claim that as the water is only in the voids of the sand, therefore it is not necessary to allow a pressure anything like the full hydrostatic head; but "the proof of the pudding is in the eating thereof", and any one who has worked in compressed air knows that very rarely is more or less air pressure needed than that required by the direct hydrostatic head.

All engineers know, of course, that steel is a much more reliable metal than cast iron, and although it does not require as much weight for the same strength, the cost of the steel will usually be greater than that of the cast iron and, when driving the tunnel through the Hudson River silt, the lightness would be a disadvantage, as the tunnels are usually much too light until the concrete lining is put in place.

It is known, of course, that steel buried in clean silt under water would last forever, but if one side of the steel is in silt and water and the other side facing the tunnel is of varying temperatures and dryness, it is not known that the steel would not corrode, nor can any one be sure that it would not be destroyed by chemicals escaping from power-houses or other sources, or by electrolysis. This was apparently realized by an inventor who about 25 or 30 years ago tried to raise $7 000 000 to build a tunnel under the East River. The gist of this invention, as nearly as the speaker can remember, was that the tunnel lining should consist of double steel shells, having a space of about 15 in. between them, which space was to be kept full of oil.

Some years ago a large steel dam was built in the West, saving thereby more than 10% of what a good masonry dam would have cost, but soon after its completion the dam was destroyed by rust, and it was found that the large hammer at the bottom of the river had been completely destroyed in a few months owing to chemical impurities in the water. This condition should have been ascertained before building the steel dam. A good masonry dam was then built, making the total cost 190% instead of 90 per cent.

* New York City.

Mr. Thomson.

At present we do not know how many different chemicals are dumped into the Hudson River or are liable to be so dumped; therefore, if the speaker were to use a steel shell in that river he would use a lining which would be sufficiently strong by itself, in case the steel should ever be destroyed.

Mr. Brodie.

ORRIN L. BRODIE,* M. AM. SOC. C. E.—In his remarks, Mr. Parmley referred to the effects of cohesion in the consideration of Hudson River silt. The speaker will not attempt to define Hudson River silt, although he has contemplated silt at the shield heading in an old Hudson River tunnel.

Early in his experience, the speaker played the office of nurse, as it were, to one of those old-fashioned, continuous, concrete mixers. It was apparent that the output was anything but satisfactory as far as constancy of desired proportions of concrete ingredients was concerned. Careful observations were had, controlling gears were changed, and other precautions taken, but still this state of dissatisfaction persisted. The only explanation at the time was that the variable, atmospheric humidity affected the cohesion and, therefore, the flow of the dry Portland cement from the feeding hoppers to the worm screw of the mixing mechanism below. No quantitative values of these humidity effects were obtained beyond those directly indicated, but faith in that style of concrete mixer was considerably shaken.

This experience was recalled by Mr. Haines' reference (page 1871) to the coarseness of Portland cement as compared with the silt in the Hudson River. Therefore, if a material like Portland cement is affected, how much more so, a finer material like river silt, directly subjected as it is to varying water content. Its cohesion would have a marked effect, especially with respect to the actual thrusts that would bear on a structure submerged therein. It is the speaker's belief that all engineers having to do with these matters recognize this, and any discussion that will contribute to this interesting subject is most timely.

Throughout this discussion, the expression, "angle of repose", has been used repeatedly and it appears that there is some confusion in the use of this term. The speaker instances Fig. 14, wherein Mr. Meem shows a side slope, in fact, two side slopes, converging downward from the bed of the stream, or surface of the silt, to the top of the submerged tunnel. The line representing this slope was referred to the horizontal by the angle, ϕ, and Mr. Meem, indicating the slope as a plane of slip, referred to it, and the angle mentioned, as the "angle of repose" of the material he was representing. Others have designated the angle of slope at which material had been observed as standing up in its natural or undisturbed state, as in a bank, as the "angle of repose". The point is that there may be a decided difference

* West New Brighton, N. Y.

Mr. Brodie.

between the slope at which a material may be found standing in its natural state and the angle of repose of that same material. Also, in any of the well known treatments of the subject of earth pressures, there is indicated what has been termed the "plane of rupture", which, it is surmised, Mr. Meem and some others had in mind at the time. It is clear, however, that the angle of the plane of rupture with the horizontal is a different quantity.* Precision and accuracy in the use of terms in this discussion, therefore, are urged, as otherwise the net result will be only a confusion of ideas.

The wide variation of opinion voiced as to what is the true angle of repose of the silt would indicate the desirability of strict definition. Rankine's earth-pressure theory, neglecting cohesion as it does, fails, perhaps, under certain conditions, to contribute as precise values as one could wish for thrusts to be encountered; nevertheless, it may be used for comparative purposes, even in such cases of doubt as the determination of actual values. That is, if the angle of repose is considered to be an index of the ratios between principal and conjugate stresses, or in the case of a subaqueous tunnel, between the vertical intensities of loading and the resulting horizontal thrust intensities, extended investigations through a range of such ratios may lead to interesting conclusions.

The use of Rankine's "Theory of Conjugate Stresses" is indicated by the authors. Their assumption, for purposes of calculation, as to vertical pressure at the top of the tunnels is 4 000 lb. per sq. ft., with weight of material of 120 lb. per cu. ft. Their investigations, results of which are depicted in Figs. 4, 5, 6, and 7, presumably with the same assumptions applying, include also consideration of compressed air in the tunnel at 25 lb. per sq. in. and an air pressure balancing the external pressure at the crown of the tunnel.

Numerous investigations of a similar character have been carried on by the speaker, so this portion of the authors' paper is of great interest to him. He has considered circular tunnels, both of cast-iron and concrete, of various sizes, and also reinforced concrete tunnels approaching the ellipse in shape. Rankine's theory was used and emphasis was laid on the comparative value rather than on any absolute values of the results of these investigations, although the assumptions of conditions adhered to actualities as far as they could be attained, considering the purposes for which the investigations were undertaken. The maximum pressure per square foot at the top of the tunnel, due to 38 ft. of water superimposed on from 25 to 31 ft. of silt, was 5 656 lb. This followed from 64 lb. for water and 104 lb. for silt, per cu. ft. Air pressure was taken at from 37 to 40 lb. per sq. in., depending on the size of the tunnel. For the cast-iron tunnels, three cases were

* The speaker has since noted that Mr. Meem has corrected Fig. 14 accordingly.

Mr. Brodie.

investigated, namely, (I) cast-iron ring, alone; (II) cast-iron ring with compressed air, inside; (III) complete tunnel structure. Cases (I) and (III) were under atmospheric pressure only. (The 25 ft. of silt was used only for the largest circular tunnel.) The cast-iron ring only was assumed to withstand stress. The investigations covered a range in angles of repose from 3 to 20 degrees.

The method of least work and the method of deflections (the latter checking the former most precisely) were developed and used in obtaining the true funicular polygons. It is pertinent to observe here that the old theory, commonly known as the theory of the masonry voussoir arch, applied in the past to investigations of this character, is not correctly applicable to the investigations of subaqueous tunnels or similar structures. It should also be noted that this question is independent of the question of what loadings may be expected to come on the structure. It may be shown that the older method leads to indeterminate results, whereas the methods applied by the speaker in this work always yield results that are completely determinate. The older method is approximate at best, and the results therefrom were found to differ appreciably from those obtained by the more correct methods, especially for low angles of repose where greater precision is necessary, although, in some cases, approximate agreement was had.

Figs. 4, 5, and 6 present striking peculiarities that compel attention. It will be noted, as mentioned by Mr. Holland,* that the funicular polygons, or "stress diagrams", in passing from crown to invert, intersect in each case the neutral axis of the tunnel ring at only one point. This inexplicable behavior of the funicular polygon has never been evidenced in the speaker's investigations referred to. With the application of the compressed air condition (Case II), for an angle of repose of 3°, the resulting polygon has been found to intersect the neutral axis in three points. For higher angles of repose, where the horizontal conjugate thrusts are lower in value than for the lower angles, intersections in four points have resulted; but never in one point, as the authors show. Considering this one-point intersection in the half ring of the tunnel, in connection with the points of application of the crown and invert thrusts, respectively, within the neutral axis at the crown and without at the invert, leads to the conclusion that, instead of being in a state of equilibrium, there is taking place an upward translation of the entire tunnel. This point, admitted by the authors, is dismissed immediately by them with the words, "the soil at the top may resist this tendency of upward displacement"; so it would appear that their analyses are caught "on the wing", so to speak. The subject of dynamics would enter here; yet, a brief consideration of these polygons, from the standpoint of horizontal crown deflections (the resultant

* See p. 1901.

Mr. Brodie.

deflection being equal to zero for equilibrium to obtain), will show that, if they meet the condition of equalization of positive and negative moments with respect to the neutral axis, their one-point intersection will result in a residual, horizontal deflection at the crown, which is a condition that is contrary to the state of symmetry assumed for the entire tunnel ring and its loadings, as evidenced by the presentation in the diagrams of a half tunnel ring.

The authors' Conclusion No. 6, that "the pressure of the compressed air in the tunnel during construction produces bending stresses in the lining", together with other statements of the same nature contained in their paper, is apt to be misleading. These statements as to the effect of air pressure are far from true. If atmospheric pressure at the surface of the river was assumed to be transmitted as a uniform, vertical intensity of force to the river bed, and thence through the silt both vertically and, as a conjugate pressure, horizontally to the tunnel, in other words, if the atmospheric pressure were assumed to act as a surcharge on the silt without the tunnel, while radial within, some bending moment would result. This condition would have to be taken into account in every investigation, whether atmospheric pressure or compressed air only was being considered in the tunnel. On the other hand, however, it would have a constant effect on all stresses, in any given case.

For the assumption of radial air pressure within and without the tunnel ring, the compressed air does not produce bending stresses in the tunnel ring, as no bending moment is introduced by the air pressure. The bending moments induced by the other loadings remain unchanged, whether the tunnel ring is subjected to ordinary atmospheric or compressed air pressure. The authors have not stated, however, how they have assumed the normal air pressure to be transmitted to the tunnel.

It is obvious that the thrusts in the tunnel ring are directly modified by the internal, compressed air, and as the bending moments remain constant, the eccentricities of these thrusts vary widely from those under the condition of atmospheric pressure only. The further statement of the authors, in this respect, that "the eccentricities of the stress [thrusts] increase with increased air pressure," is quite correct.

The following conclusions have been drawn by the speaker from his investigations, principally having to do with two sizes of cast-iron tunnels and along the lines previously stated by him (covering Cases (I), (II), and (III)):

Although the eccentricities in Case (II) (compressed air) varied widely, almost erratically, it might be said, as compared with the

Mr. Brodie.

other two cases, the resulting tensile and compressive stresses in the cast iron varied continuously with the angle of repose and paralleled the similar variation of stresses of the other two cases.

All conditions being considered, the highest values of tension and compression in the cast iron resulted for Case (III) (complete structure, under atmospheric pressure).

Therefore, in order to consider the effect of different conditions of loading on the structure, not only from bending moments, but, in conjunction with them, the thrusts resulting must be treated.

An expression for the maximum eccentricity of the thrust line in the tunnel ring is presented by the authors. It was derived, they state, from funicular polygons of tunnels of various diameters under specific, rigorous conditions. The speaker was led to compare the results obtained by this formula with his own results, by doubt as to the reliability of the authors' polygons as published. It is presumed that the compressed air condition was not included in the formula; but the speaker includes his three cases in Table 2, together with values which he has computed by means of the authors' formula, realizing, of course, that its upper limit is for a diameter of 36 ft. Outside, round numbers are given for $\phi = 3°$ (the formula is based on $\phi = 2° 52'$), the other conditions are respectively as previously stated. It was developed by the speaker's investigations that, except for compressed air, the eccentricities increased continuously with the angle of repose. Table 2 shows the results, in inches, for a 23-ft. and 29-ft., cast-iron, and a 42-ft. (outside diameters), concrete, block tunnel.

TABLE 2.—MAXIMUM ECCENTRICITIES OF RING THRUSTS.

Size and kind of tunnel	23-ft., cast-iron.	29-ft., cast-iron.	42-ft., concrete block.
Air pressure, in pounds per square inch.	37	40	.....
Ring alone, in inches	½	1	.....
Complete structure, in inches	2	2	3
Ring with compressed air, in inches	4.5	26	.....
By authors' formula, in inches	5.3	9.5	23.7

The discrepancies appearing in Table 2 are too great to be accounted for by the difference in assumed weights of silt of 120 and 104 lb. per cu. ft., but rather indicate that the funicular polygons on which the formula was based were not the true polygons for the cases considered.

The conception of the elliptic arch for use in ordinary earths (where the depth of tunnel ring may be neglected with respect to the depth of the overlying earth) and the hydrostatic arch in water, coupled with

Mr. Brodie; his investigations of a form of the latter type subjected to silt loads, causes the speaker to express doubt as to the advisability of successfully utilizing the ellipse as a means of reducing bending stresses in the rings of under-river tunnels, especially when the practical features involving difficulties with shield-driven tunnels are considered. Unless necessary in some types, the speaker deems it unwise to depart from the circular shape, for, in some cases, although the bending moments in the upper half were found to be improved, the flatter, lower portion usually exhibited an increase in values of bending moments and the funicular polygons in most cases tended toward the circular shape, generally speaking. This necessitated heavy reinforcement, locally, as both the thrusts and eccentricities were considerable.

The authors have outlined a method for determining the values of critical angles of repose for tunnels of different sizes, under which angles the "abutting power" of the silt may not be used to attain a state of direct compressive stress in the ring. An allusion is made to the method of least work; but nothing further is mentioned as to its use in the paper. It is stated also that coincidence of the "stress polygon" (line of pressure) with the neutral axis of the tunnel lining will give the least internal work.

In this connection, the speaker submits Fig. 30, showing variations of bending moments with the angle of repose (expressed also as the ratio mentioned previously) for the three tunnels already considered and for the complete structures, in each case; and Fig. 31, showing corresponding variation of the ring thrusts for the 29-ft. tunnel, as typical of the others. The bending moments at the haunch are of opposite sign to their corresponding moments at the crown and invert; but for convenience all are plotted in Fig. 30 as of like sign. By means of Fig. 30, the horizontal force necessary to produce the coincidence of the line of pressure, or what is the same thing, zero bending moment, in the ring, may be directly approximated. The diagram shows at once, however, that there is no point at which zero bending moment exists throughout the ring; that is, flexural stresses would occur at some point or other. On the other hand, for small angles of repose, these stresses are negligible, as tensile stress of flexure is more than neutralized by the direct compression. Figs. 30 and 31 give values plotted for crown, haunch, and invert, and the average of the angles where those of Fig. 30 cross the zero bending moment line are shown in Table 3, against corresponding values obtained by the authors for tunnels nearest in size to those considered by the speaker. (The values for the ring alone (Case I) were also considered but did not exceed the values for the complete structures by more than 2 degrees.) Below the angles of repose as tabulated, then, the tunnel rings will not be in pure compression and, above

Mr. Brodie.

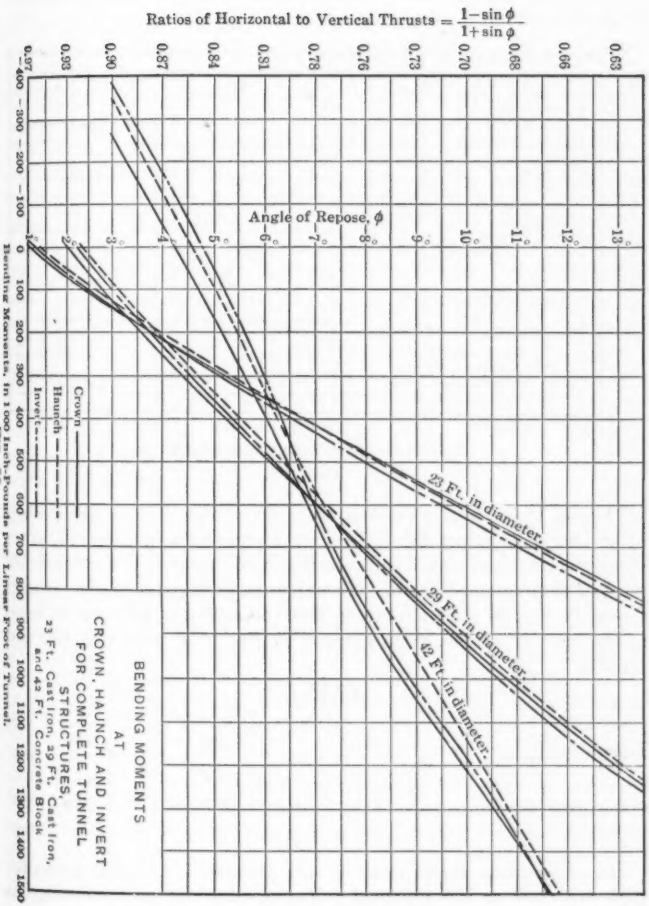

FIG. 20.

Messrs. Johannesson and Hewett.

the direct stresses, the writers cannot follow him, because by his method, the greater the angle of repose, the larger the load to be carried. Going to the extreme, this would mean that in solid rock the tunnel would have to carry all the rock above, while the greatest arch action would occur in water. Similarly, the formula on page 1862, giving the value of side pressures, would give infinitely large side pressures in rock and no side pressure in water. As regards the top pressures, the writers agree with Mr. Meem that often a reduction may be made to allow for cohesion, but how much of a reduction? In soils with a small angle of repose and where the cover is shallow, the reduction would not be worth taking into consideration.

It might be thought, from the objections made by Mr. Meem, that the pressures as determined by the writers were much greater than those determined by Mr. Meem. It is instructive, therefore, to compare them. Using the numerical values given by Mr. Meem on page 1864, for the formulas for P_2 and P_3 on page 1863, it is found that

$$P_2 = 125\,325 \text{ lb. per lin. ft.}$$
$$P_3 = 187\,500 \text{ " " " "}$$

while the corresponding value given by the writers is 153 750 lb. per lin. ft., or about 2% less than the mean of P_2 and P_3.

Mr. Parmley questions the value of the side pressure used by the writers, stating that it has been found to be less than that assumed. The writers agree with Mr. Parmley that cohesion, etc., probably act as a tendency to produce an active horizontal side pressure less than that assumed. Here, again, the question is: How much allowance may be made? In soils with a small angle of repose this allowance must be quite small, and it is safer not to count on it.

Mr. Parmley assumes that the vertical diameter will be decreased under the earth pressures. Suppose, to go to the extreme, that the tunnel is in water with the top at the level of the surface of the water, then the horizontal diameter of the tunnel would evidently have a tendency to decrease. Similar conditions may occur in a soil with a small angle of repose. It is necessary, therefore, in this case, to consider properly the active horizontal pressure.

Mr. Parmley makes a valuable suggestion regarding the relative deflection of the tunnel structure and the compression of the surrounding soil. This relation naturally depends on the stiffness of the structure and on the character of the soil.

The development of a design for a concrete block tunnel with a horizontal tie or strut, as described by Mr. Parmley, is most interesting. The writers, however, question the advisability, from an operating standpoint, of a tunnel having two roadways, one above the other, except in case of absolute necessity, and they do not believe that the

cost of concrete blocks erected is only a substantial fraction of the cost of cast-iron segments erected, except in dry soil and in tunnels of moderate size. Messrs. Johannesson and Hewett.

The writers acknowledge the valuable work performed by Mr. Brodie in determining stresses in tunnel linings and the accurate mathematical methods used by him. They also acknowledge an error in their paper, pointed out by Mr. Brodie, relative to the stress diagrams shown in Figs. 4, 5, and 6. By omitting the effect of the vertical forces on the horizontal reactions the curves intersect the neutral axis only once. Making this correction, it is found that the curve intersects the neutral axis twice and that the eccentricities are reduced. Notwithstanding this reduction of the eccentricities, their magnitude still remains, under the conditions discussed in the paper, a function of $d^2 \sqrt{d}$, so that the principle of the argument developed is unaffected.

Mr. Brodie states that the compressed air does not produce bending stresses in the tunnel ring, as no bending moment is introduced by the air pressure. The air pressure, however, decreases the direct stresses and, therefore, intensifies the effect of the bending moments. Mr. Brodie further states that it was developed by his investigations that (except for compressed air) the eccentricities increase continuously with the angle of repose. The writers believe that this extraordinary result which, when carried to the extreme, would mean that the lining in rock would have the most severe bending stresses, is arrived at by taking only the active horizontal pressures into account. The fact that the active pressures are considered in action indicates that Mr. Brodie has assumed that contact exists between the lining and the soil. If this contact exists, as has also been assumed by the writers, the passive pressures cannot fail to develop if called on, and they will completely change the bending moments. In Table 2, Mr. Brodie shows a comparison of eccentricities as determined by the writers' formula and as determined by him in specific cases. The writers do not know the details of the assumptions made by Mr. Brodie, but believe that the discrepancies are accounted for partly by a difference in the assumptions as to the weight of the lining and partly by a difference in the assumptions as to the weight of the silt. The writers used, for the purpose of comparison, a constant weight per linear foot of circumference of tunnel ring, while Mr. Brodie probably used the actual weights of tunnel lining, which increase rapidly with the size of the tunnel. Investigations indicate that at a small angle of repose the weight of the lining has a large effect on the bending moments.

With respect to the use of a tunnel lining in the form of an ellipse, the writers do not fear any practical difficulties; in fact, the elliptic form has been used successfully for shield-driven tunnels. As far as

Messrs. Johannesson and Hewett.

the theory is concerned, it may be interesting to note that after their investigations had been made, they found that Professor Rankine had long ago arrived at the same conclusion.

In Table 3, Mr. Brodie gives a comparison of the values obtained by the writers for angles of repose above which no bending stresses will occur and angles of repose, determined by Mr. Brodie, giving the least bending moments in the lining. The writers submit that the two sets of values, as determined by Mr. Brodie and by them, do not represent the same matter. Mr. Brodie's values represent those angles of repose which would produce the least bending moments, providing active horizontal pressures only were acting. As just stated, the writers cannot admit such a condition as existing. As stated in the paper, the writers' values are arrived at by taking into consideration the passive horizontal pressures and represent the angles of repose at which no bending moments will occur.

The writers venture, in closing this discussion, to make a few observations on the reasons which led them to offer this paper to the Society and to point out some of the difficulties which surround this subject, which presents an almost virgin field. There is need for much further study and experimentation, and until that work has been done, honest differences of opinion as to the stresses in the lining of a tunnel under any given set of conditions are to be expected.

The art of the tunnel builder is an ancient and honorable one, and goes back to the earliest dawn of man's existence as a tool-using animal. Like all other arts, its development during the last half century has been rapid. In comparison, however, with many other branches of engineering, the development of what might be called the scientific side of tunnel design has not kept pace with practical application. This is perhaps partly, or even largely, due to the fact that among engineering works tunnels are comparatively rare. For every tunnel there are hundreds of bridges, and, consequently, the science of bridge building has kept better pace with the necessity of the art than that of tunnel building.

In old days tunnels were placed in ground which would give easy construction conditions, and where the ground was too difficult for the skill available at that time no attempt was made to build a tunnel. This cannot always be done nowadays, and it is often the case that a tunnel has to be built between two points regardless altogether of the geological conditions which lie between them. Where the ground is adverse, either by reason of carrying large quantities of water, though itself sound and self-sustaining, or where it is of the kind known as "soft" or "heavy", great engineering skill may be required, both in design and execution, to put the work through.

Messrs. Johannesson and Hewett.

It is essential to sound engineering to have as thorough a knowledge of the ground as possible, including the magnitude and distribution of the pressures which the ground will exert on the tunnel lining during the various stages of construction up to its finished and operating condition. The effect of such pressures on the lining, as well as the action of compressed air where such is used, must also be known.

Tunnel engineers of experience and prominence, both here and abroad, have suggested, from time to time, that it is useless to attempt to calculate the stresses in a tunnel lining because the earth pressures are not known. As these pressures must be assumed, they say, the proportions and dimensions of the lining may be assumed just as well and the design evolved by judgment and experience. This, no doubt, in many or most instances is the literal truth. It need not be taken, however, as the final word. What we do not know we may find out by experiment and theory founded on the experiment, just as all our knowledge of natural phenomena has been gained.

In the paper the writers have used the theory of earth pressures enunciated by Professor W. J. M. Rankine as the basis of the discussion. It has been objected that this theory is based on the existence of certain ideal conditions which are not found in Nature and that cohesion, the quantity of water contained, etc., would affect the adaptability of this theory to the subject at hand. To this it is replied that, according to such experimental work as has been done, it has been proved that, as far as the Hudson River silt is concerned, when a low value (in this case an average of about 3°), was assigned to the angle of repose, it was found that the pressures calculated by Rankine's formula agreed with those actually observed on the tunnel lining. This suggests the value of a comprehensive series of full-scale experiments on earth pressures on tunnel lining. As long as engineers have no additional information, the Rankine theory affords a working basis for discussion of soils of this character.

A structure must carry the most severe loading that may be brought upon it. If it can be determined, with certainty, that the cohesion, for example, will reduce the earth pressure, an adjustment may be made. If a possible variation of the water content in the ground can cause a variation in the characteristics of that ground, that content which produces the most severe loading must be taken into account.

With regard to the scientific or rational design of tunnels, the most urgent necessity, at the present time, is experimental work to determine the actual earth pressures on as many existing tunnels and on as many tunnels under construction as possible, and to determine the physical characteristics of as many kinds of ground as possible. In this manner important economies of design may be discovered, and this economy may, and doubtless would, repay many times over the cost

Messrs. Johannesson and Hewett.

of the necessary experimental and office work. The recent Progress Report* of the Special Committee on Stresses in Railroad Track furnishes descriptions of methods of measuring pressures in the ballast, which are highly suggestive as to methods which might be applied to tunnels. The writers venture to suggest that the Society might do a great and valuable work by an investigation of earth pressures.

The writers cannot close this discussion without an expression of their indebtedness to the labors of the late Brig.-Gen. C. W. Raymond, M. Am. Soc. C. E., during the time he acted as Chairman of the Board of Engineers of the Pennsylvania Railroad Company's tunnels in New York City. These labors lasted from 1905 to 1910 and comprised many hundreds of the most careful and precise measurements and observations made with sensitive and specially designed gauges on the Hudson River silt. These observations, and the conclusions drawn therefrom, which have never been published, confirmed the expectation which had been formed that the silt would behave in accordance with the Rankine theory. This series of experiments was the actual source and origin of the writers' paper.

The Rankine theory had been used by S. H. Woodard, M. Am. Soc. C. E., in a report on the expected action of the silt on a tunnel driven through it, which was submitted in 1903 to the Board of Engineers of the Pennsylvania Tunnels, before the actual construction work was started and, therefore, before Gen. Raymond's experimental work, which determined the actual characteristics of the silt, had been done.

The design of tunnel linings, especially as concerns linings for shield-driven tunnels in soft ground, has been touched on by M. Raynald Legouez, by Paul A. N. Seurot, M. Am. Soc. C. E., and by others, but there seemed to the writers to be a need for the endeavor to find a way by which practical results could be drawn from analytical discussion. The writers recognize that the paper only touches the fringes of the subject, and they feel most gratified that so many able and experienced engineers have filled in, by their discussion, the gaps and deficiencies in the paper. They hope that this important and interesting subject will be pursued further, in the light of wider experimental knowledge, by such means as will develop information regarding the actual stresses in a tunnel lining, so that the art of tunneling may thereby be advanced.

Paper No. 1460

REVISION OF THE NIAGARA RAILWAY ARCH BRIDGE*

By Charles Evan Fowler, M. Am. Soc. C. E.

With Discussion by Messrs. O. H. Ammann, C. Bentham, J. A. L. Waddell, Theodore Belzner, F. E. Schmitt, P. G. Lang, Jr., James E. Howard, Clyde T. Morris, Almon H. Fuller, and Charles Evan Fowler.

Synopsis.

The revision of the Niagara Railway Arch Bridge made in 1918-19, as here described, comprised first a complete investigation of live loads for railway bridges, in order to determine the probable maximum loading for such a terminal bridge—a double-track, two-hinged, 550-ft. arch over the Niagara Gorge. In 1918 an extensive series of strain-gauge readings, the methods of which are fully described, was made. The dead load stresses were investigated by jacking apart one top chord of the arch span by means of a special toggle, the center top chord dead load stress being read with the strain gauge. This resulted in the jacking open of both top chords in 1919 to change the center shims and readjust the stresses in all members of the arch trusses.

The investigations as to the proper unit stresses to adopt and the logical column formula to use for the revision, are given at some length. The strain-gauge investigation also determined the secondary stresses, and readings of stresses made during the passage of trains at various speeds were made the basis of a formula for a curve of values for impact at various speeds. The new Fuller-West strain gauge, developed as a result of the investigations, is described.

* Presented at the meeting of June 2d, 1920.

The methods of reinforcing the sway and floor system of the arch span and of the approaches, particularly the methods of relieving dead load stress and of doing the field work, and the construction of a copper-steel salt-water protecting floor are described, also the method of grade rectification.

The method of reinforcement of an abutment 64 years old is given in some detail, as well as armored coatings of the arch skewbacks to protect them from weathering, and of skewback thrust walls to carry the sway stresses to bed-rock. Brief descriptions are given of the improvements made to the bridge entrances, and other bridge property accessories. The paper as a whole covers the work of revising the structure up to modern capacity at less than one-third the cost of a new structure.

The Niagara Railway Arch Bridge (Fig. 1) was constructed in 1896-97 from the plans of the late L. L. Buck, M. Am. Soc. C. E., to take the place of the Roebling Railway Suspension Bridge, and has already been described for the Society.* The history of the various bridges which had occupied this site is quite fully given, so that no description of them will be repeated here; but it is desirable for the full understanding of this paper to show briefly the evolution which took place from the first suspension bridge built in 1847-48.

The first bridge was built of wire cables, with no stiffening trusses, carrying a single 7-ft. roadway. That no disaster occurred due to the heavy winds up and down the Gorge may be considered miraculous, as such a disaster did befall the Wheeling Suspension Bridge, which was built by the same engineer, Charles Ellet, whose fame resulted from his work in the development of long-span suspension bridges. Doubtless the study of the faults of this very primitive bridge over the Niagara Gorge led the late John A. Roebling, M. Am. Soc. C. E., to plan the railway suspension bridge with heavy stiffening trusses, and with guys to the cliffs as well.

That there was much competition between the suspension type and the tubular continuous girder, is evidenced by the remark in Mr. Roebling's final report to the effect that "as regards the success of your work more has been accomplished than was promised. The idea of a perfectly rigid structure, such as a tubular bridge, was never held out".

---

* *Transactions*, Am. Soc. C. E., Vol. XL (1898), p. 125.

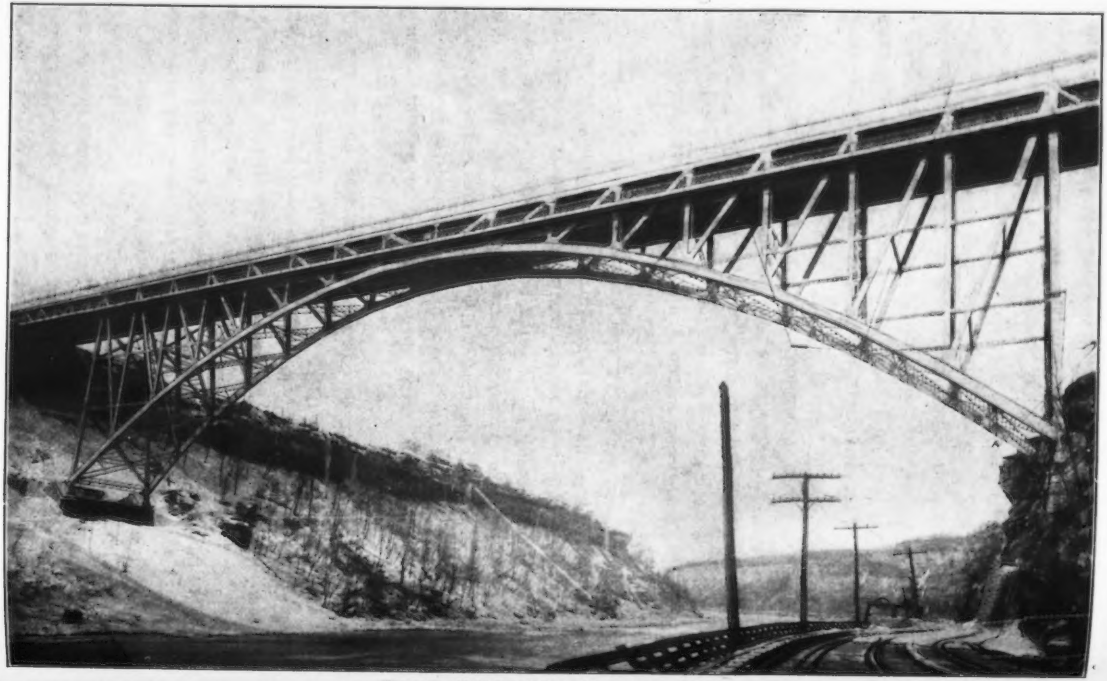

FIG. 1.—NIAGARA RAILWAY ARCH BRIDGE.

The design for a tubular continuous girder bridge for this site was made in 1850, by James Hodges. This is shown in Fig. 2, and is undoubtedly one of the most pleasing, artistic and chaste designs ever made for a bridge with wholly rectangular lines. One is also led to wonder if it would not, with some reinforcement, have been in use nearly up to the present, had it been built instead of the suspension type. The reason for its not having been adopted, as may be inferred from Mr. Roebling's remark just quoted, was due almost entirely to the question of cost. There may also be some question as to whether such heavy stone piers would long have stood so close to the water's edge, especially in view of the fact that the side slopes under water have scoured out as much as 30 ft. near this site, during the last twenty years.

The statement may be safely made, however, that if an engineer were considering the various phases of the problem of bridging the Gorge at this site to-day, the quest would soon narrow to the three-span continuous truss and a two-hinged arch such as is now in use, with the modification, however, of its being constructed as a three-hinged arch under dead load. The latter feature governed very largely the course of the writer's investigations during the summer and fall of 1918, looking toward increasing the carrying capacity of the arch structure.

The stiffened suspension bridge would now only be considered for railway use where the span was very long, or where the ratio of dead load to live load would approximate 1.8 to 1 up to 3 to 1. There is, however, every probability that as steel becomes increasingly costly, the minimum span for suspension bridges for carrying railways will again gradually approach 1 000 ft.

The process of evolution at Niagara shows also the progress from wood to stone and steel, and, later, to reinforced concrete and steel. The towers of the first suspension bridge were of wood, and although an advance was made in using stone towers for the railway suspension bridge in 1856, a still further advance was made by replacing the stone towers, which had become badly cracked and shattered, with steel ones in 1886. The use of stiffening trusses in the railway suspension bridge was a distinct advance, but they were of wood, and were later replaced with steel trusses. Both the towers and stiffening trusses were replaced under the supervision of Mr. L. L. Buck, and fully

described for the Society.* The work carried out during 1919 on the arch, under the writer's direction, marked a still further replacement of wood with steel, and the substitution of steel or reinforced concrete for some of the stonework.

The writer was first called on in June, 1918, to make merely the regular annual inspection of the bridge, and it was supposed to be confined to the need for ordinary repairs, such as riveting and painting. However, there was found to be very serious corrosion of the top flanges of the floor-beams, stringers, and stringer laterals on the spans, and the top flanges and laterals of the six approach girder spans, from the salt water dripping from refrigerator cars and from leakage of water and injector discharge from locomotives. The studies made in developing plans for repairing this damage, where metal originally ½ in. in thickness was corroded in some cases to a thickness of only $\frac{1}{16}$ in., soon demonstrated that the loads passing over the double-track railway deck were from 30 to 70% heavier than those for which the structure was designed.

Instructions were thereupon given to proceed with a thorough analytical study and strain-gauge analysis of the entire bridge. This was considered to be necessary by the writer on account of the 550-ft. arch span being an indeterminate type of structure; on account of the large secondary stresses that it was apparent were induced from many of the details; and from a desire to fix definitely the amount of impact. The first problem, therefore, was to study the past and probable future increase of live loads.

Live Loads.

The trains crossing the Suspension Bridge at the time of its completion in 1855 were so light as to be somewhat amusing in comparison with present-day trains, but they were a serious problem to the engineer of that period. In his final report, Mr. Roebling speaks of passenger trains of 15-ton cars frequently passing over the bridge, and the average number of trips in March, 1855, as being more than 30 daily, probably including freight trains as well as passenger trains.

The loads used by Mr. Roebling in testing the Suspension Bridge are referred to in his report in several paragraphs as follows:

* *Transactions*, Am. Soc. C. E., Vol. X (1881), p. 195.

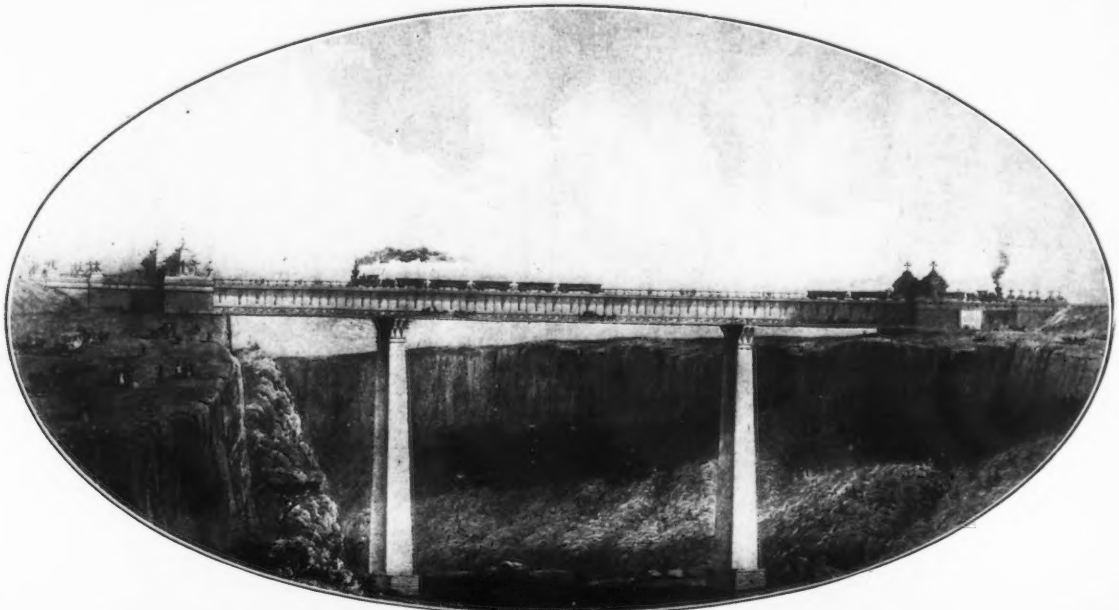

FIG. 2.—NIAGARA CONTINUOUS TUBULAR DESIGN.
JAMES HODGES, 1850.

"An engine and tender of 34 tons weight, together with one passenger car, crowded with persons, making a total of about 47 tons, caused a depression in the center of 5½ inches." * * *

"A single engine of 23 tons weight, including tender, caused a flattening of the camber in the center of 0.3 feet." * * *

"On the last mentioned day (March 18th, 1855) the railroad floor was opened for business by passing an experimental freight train, composed of 20 full loaded cars, pushed by a 26-ton engine, from the Canada to the New York depot. The gross weight was estimated at 326 tons."

This indicates that the total weight of each car, with load, was only 15 tons. Other tests were made with a 22-ton American engine and a 34-ton, six-driver, English built, freight engine. The locomotives used in the test trains by Mr. L. L. Buck, in testing the Arch Bridge on July 29th, 1897, weighed 90 tons each, the cars 52.5 tons each, and the total test load on the 550-ft. arch span was 1 670 short tons. The engines used by the writer for load tests and deflection tests on August 30th and 31st, 1918, weighed from 177 to 221 tons each, and the test load on the 550-ft. arch span was 2 490 short tons.

The diagram, Fig. 3, shows by the lower curve the average increase in the total weight of locomotives in short tons for this locality from 1850 to 1918. This curve was established from the weights of locomotives passing over the Niagara bridges during this period and filled in by locomotives used by the writer in calculating bridge stresses in the same territory from 1887 to 1918. It agrees quite closely with the one established by J. E. Greiner, M. Am. Soc. C. E., from the records of the Baltimore and Ohio Railway. The curve extended to 1940 indicates that the total weight of locomotives by that time might reach 365 tons, if the same rate of increase is maintained; but owing to mechanical limitations well known to locomotive builders, such as lack of space for much larger cylinders, it seems more probable that the 1940 limit for consolidation or decapod locomotives will not exceed 300 tons, as indicated by the dotted reverse curve. The total weight of the various Cooper locomotives has been located on the curve, as a means of general comparison. The investigation developed the fact, which is doubtless more or less appreciated by all railway and bridge engineers, that the Cooper loadings are out of date and should no longer be used for calculating bridge stresses. The Cooper E-65

locomotive (and all others) is only 56 ft. in length, whereas the Grand Trunk Mikado locomotives used in the tests of 1918 on the arch weighed 221 tons, or practically the same as the E-65, but were 77 ft. long over all.

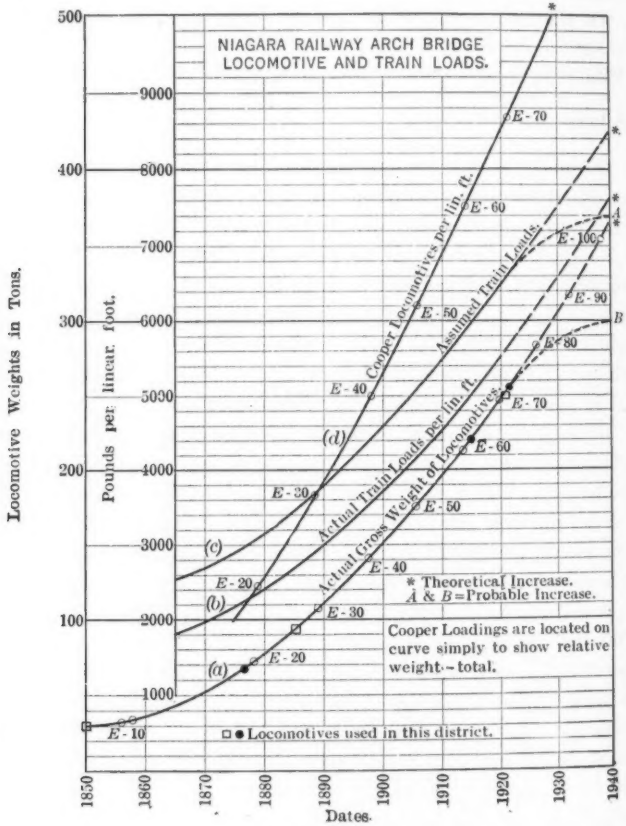

FIG. 3.

The peculiar use of the Niagara Arch as a terminal bridge, or connection between the Canadian and American yards, makes it unnecessary to provide for as heavy locomotives as would be used on a main-line structure, so that Cooper's E-60 as adopted for the arch

and the truss spans reaching to the shores, will undoubtedly be the maximum absolutely required up to 1940; but to make a structure of uniform strength for modern locomotives it was necessary to use Cooper's E-70 loading for the stringers and floor-beams on the spans and the approach girders, or on spans from 20 to 52 ft. in length. Then, by stopping traffic at any time on one track, it will be possible to pass heavy loads or locomotives slowly over the other track, up to about E-80 loading or its equivalent.

The logical procedure for new bridges, however, seems to be to abandon the Cooper loading entirely and adopt a table of moments (and one of end shears to correspond) similar to that given in Column 10 (*F*) of Table 1. This was established by taking the maximum moment from Columns 1, 2, 3, and 4 for each span length, Columns 1, 2, 3, and 4 being the moments from the heaviest existing locomotives and trains, as calculated by H. T. Welty, M. Am. Soc. C. E., Structural Engineer of the New York Central Railroad. This indicates that for a logical application of the old Cooper loadings, E-70 should be used for spans from 10 to 30 ft., E-80 for spans from 30 to 100 ft., and E-60 for spans from 100 to 300 ft. and over. Should it be desired to provide for future increase, as is advisable, a percentage must be added to the values in Column 9 (*F'*), logically 25% at the present time, these values plotted, a smooth curve established comprising them, and the moments tabulated for each span length from 10 to 300 ft.

The values for moments in Column (10) (*F*) of Table 1, and Fig. 4, would be greater than for E-90 loading up to about a span length of 120 ft., and for spans greater than 120 ft., the *F* moments would be less than for E-90 loading. Some of the large railway lines are already planning to use a similar scheme, and it is confidently expected that some such method will be in universal use within a few years.

The adoption of a maximum loading such as this, and approximating E-90, calls of course, for a more logical system of unit stresses, and not less than those used in the Niagara Arch revision, such as are explained in a later section of this paper. They agree well with the unit stresses used for the Hell Gate Arch and the Quebec Cantilever. The table would show the relation to the Cooper loads, and they could still be used as a reference standard for spans calculated for them.

The actual train loads for the same period are shown on Fig. 3, as Curve (*b*), and the assumed train loads as Curve (*c*). These curves

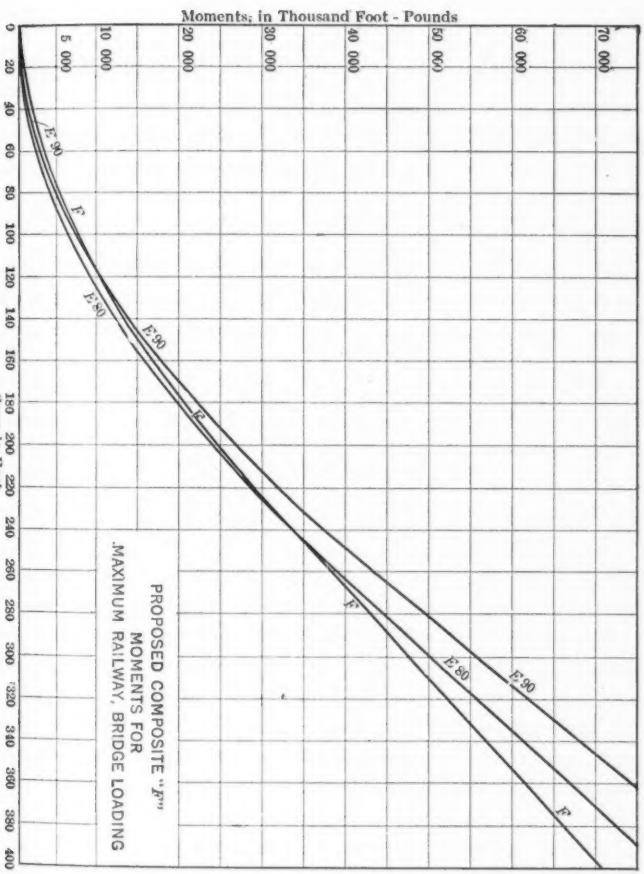

FIG. 4.—COMPARISON OF COMPOSITE AND COOPER LOADINGS.

indicate that the following, or train loads, with each of the Cooper loadings E-60, E-70, and E-80, are too high and that if Cooper's loading is to be used for the future, the train load for E-60 should be 5 500 lb. per lin. ft., for E-70 only 6 000 lb. per lin. ft., and for E-80 only 6 500 lb. per lin. ft. The weight per linear foot of Cooper locomotives is shown in Curve (*d*) for the purpose of general comparison.

The careful study of all traffic using the Niagara Arch Bridge, and especially of that passing over it during the months that the tests were in progress in 1918, indicated that, for both tracks loaded, 90% of E-60 should be used on the arch, but 100% on the trusses of 115-ft. span.

Deflection.

The deflection of the Roebling Suspension Bridge was very large, amounting to 5½ in. under a light load of 47 tons total for one locomotive and one passenger car. This always necessitated the slow speed of 5 miles per hour, and as the trains increased in weight greatly by 1896, the deflection became alarming, amounting to about 18 in. The Schneider Cantilever Bridge near it had a deflection under the original test load of about $7\frac{5}{16}$ in. The new arch built in 1896-97 was tested, therefore, only for the deflection under the test load of alternating engines and cars weighing a total of 1 670 tons, and a maximum vertical deflection of $\frac{13}{16}$ in. resulted. The calculated deflection for the full load on both decks of 10 000 lb. per lin. ft. was $1\frac{15}{16}$ in. This was for a total load on the arch span of 2 750 tons, while the load of 2 490 tons used by the writer on August 30th and 31st, 1918, caused a maximum deflection of 1½ in., or an increase in effective loading of 84.5% above the 1897 test load used by Mr. Buck.

The sidewise deflection of the Suspension Bridge was so excessive as to require the use of stay cables to the cliffs, and although under the proportionately light loads of 1897 the arch was comparatively stiff sidewise, the loads had increased so greatly by 1918, with speeds allowed by sufferance up to 25 or 30 miles per hour, that the side sway had become somewhat alarming in amount. The writer, therefore, reduced the maximum speed to 10 miles per hour in July, 1918, and new sway bracing was introduced, as will be described later, that has practically removed all sidewise deflection.

Impact.

When the inspection of 1918 was undertaken the impact on the structure was apparently very excessive, and was composed of various factors, such as direct impact from the excessive speeds, hammering on open rail joints, bad track alignment, flat wheels, and various kinds of vibration. The impact readings made with strain gauges therefore covered all elements of train load outside the merely static effect. The readings were made with the Berry strain gauge and the curves of increase due to speeds of 5, 10, 15, 20, and 25 miles per hour are shown by solid lines in Fig. 5. These readings indicated that probably the critical speed for the structure was in the neighborhood of 25 miles per hour, at which speed the impact practically agreed with that derived from the old Schneider formula:

$$I = \frac{300}{l + 300}.$$

However, as no readings were made at higher speeds, it can only be stated that at 25 miles per hour the impact agreed with that derived from the Schneider formula; but it is by no means certain that at some point of higher speed values as great as those given by the Lindenthal formula would not be reached.

The values of impact are given in Table 5, which is the stress sheet for the structure as rebuilt. The impact stresses have been computed by three different formulas—the Schneider formula, the Lindenthal formula, and the proposed new American Railway Engineering Association formula; and also for the values adopted for the structure (column headed Niagara in Table 5), as based on the strain-gauge readings, which are for 17 miles per hour, or practically 50% of the Schneider values. The formulas referred to are as follows:

Schneider, $$I_1 = \frac{300}{l + 300}$$

Lindenthal, $$I_2 = \frac{L^2}{D + L} \times \frac{8\,Q + q\,a}{4\,Q + 4\,q\,a}$$

New A. R. E. A., $$I_3 = \frac{300}{300 + \frac{l^2}{100}}$$

Fowler, $$I_4 = \frac{\left(\frac{I^2}{s^2}\right) S^2}{I_1}$$

in which,

I_4 = percentage of impact for any speed below that read;
L = live load stress;
D = dead load stress;
l = loaded length;
S = speed, in miles per hour, for reduction;
s = speed, in miles per hour, for strain-gauge reading;
Q = locomotive weight;
q = train load per linear foot;
a = length of train behind tender.

Although the readings made by the writer were not great in number, they were so harmonious as to make it possible to establish a safe curve for the variation of impact due to variations in speed below the critical point or that speed giving maximum impact. This curve is shown in the dotted line in Fig. 5 and the formula is that given as I_4 with the denominator I_1, and for which may be substituted the values derived from either I_2 or I_3 if it is desired to use another than the Schneider formula for obtaining maximum impact.

When used for some other structure, check readings should be made for the particular case at several speeds, and the coefficient of S definitely fixed. The actual running speed over the structure should be established of course at some maximum limit, somewhat below the speed used for fixing impact values for the stress sheet.

Whatever impact formula is used, it should certainly be one which gives values high enough to cover as well all the factors of ignorance as to stresses, and thus permit confidence in the logical use of proper maximum unit stresses. With such an idea in view, the impact values given by the Lindenthal formula for the arch do not seem to be very excessive for high speed.

The question of impact from the highway live load was carefully considered, and owing to the fact that the highway deck carries no street cars, and that the maximum highway live load is small in proportion to the train load adopted, no impact allowance was made for this part of the moving load. When still further additions are made to the structure and street cars provided for, then an impact allowance will be made on the street car live load, and also for any additional future loading that may be of a highly dynamic character.

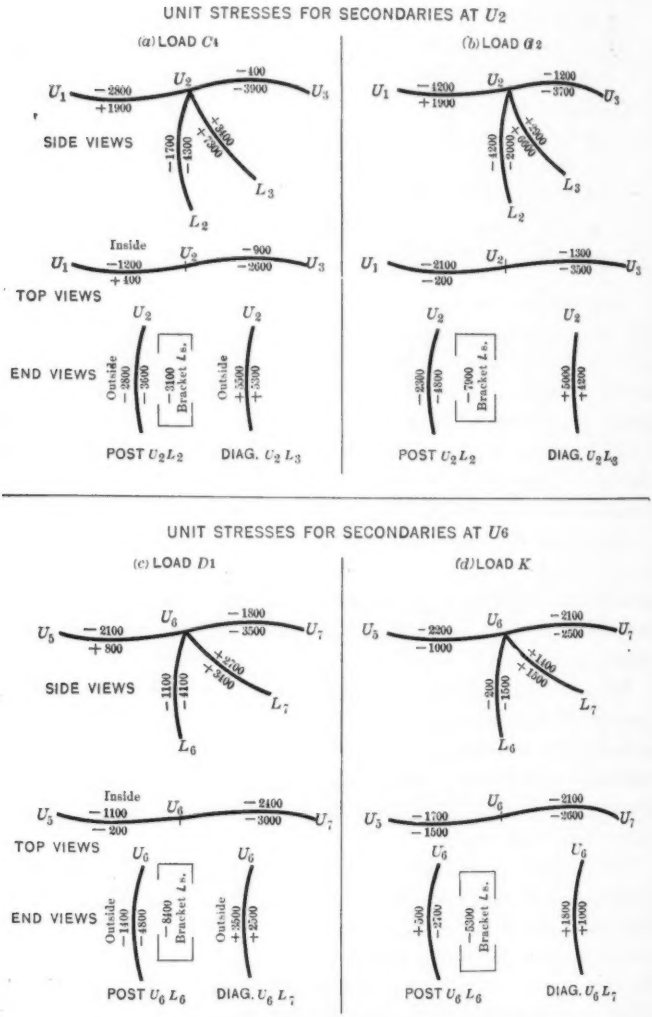

FIG. 6.—DIAGRAMS OF SECONDARY STRESSES, NIAGARA ARCH.

To insure that the railway speeds over the bridge shall not exceed the maximum of 17 miles per hour, a Bristol speed recorder, similar to that installed for the Pennsylvania Tunnels at New York City, has been provided.

Secondary Stress.

The general inspection of the Niagara Arch indicated that there were comparatively large secondary stresses. The smallest increment of stress of this kind was due to the weights of the members themselves, and another comparatively small amount was caused by the main hinge rollers being locked against proper action. The largest increments were from the distortion of the arch span under moving trains and partial live loads, from the curved sway brackets between the upper and lower floor-beams connecting to the main posts, and from the curved knee-braces connecting the girders and posts of the approach viaducts.

Strain-gauge measurements were made for secondary stresses, with 8-in. Berry instruments, and on points placed near the main gussets and also at other points where judgment indicated maximum values. The character and extent of the secondary stresses in the main posts and curved brackets of the arch span, are shown in Fig. 6 (*a*) to (*d*). One of the greatest variations in unit stress is shown in Fig. 6 (*b*), where it was 2 300 lb. on the outside of Post $U_2 L_2$, 4 800 lb. on the inside of the post, and 7 900 lb. on the flange of the curved bracket.

The fact will also be noted from these diagrams that all the top chords have secondary stresses in both vertical and horizontal planes. Secondary stress in the horizontal planes was always of the same character, and on analysis this was found by the writer to be due to the force acting at the extreme end of the heavy main gussets, and induced by the bending from the curved brackets. The great secondary stresses induced by these curved brackets, however, was only one of the reasons calling for their reinforcement.

The secondary stresses in the posts of the 115-ft. spans and the viaduct posts were provided for by the reinforcing angles which were added to these members to increase the sectional area for the direct compression stress due to the new live load capacity of the structure. These angles were required for giving as large a radius of gyration as possible to the members; but, as providing for the secondary stresses, the angles required as short outstanding legs as possible in order

to keep down the fiber stress. The method of adding these angles is described under the head of practical strain-gauge applications.

The secondary stresses were not calculated for the main arch members, but were compared with the plotted curves of the secondary stresses as calculated for the Hell Gate Arch, a similar type of structure. Diagrams, four in number, similar to Fig. 7, were prepared for the top chords, the bottom chords, the vertical posts, and the diagonals. On each of these four sheets, the secondary stresses read by the strain gauges upon the Niagara Arch were plotted, and a curve was established similar to the combined dead and live load curve for the Hell Gate Arch. The panel lengths of the Niagara Arch were laid off to the same scale as that used for the Hell Gate Arch, at the bottom of the diagram, thus making it possible to compare directly the percentage of secondary stress for each member in each panel of the Niagara Arch. The probable error in any case is indicated as being on the safe side, and for all practical purposes the resulting secondary stresses as entered in the stress sheet may be considered within the possible error of the Niagara strain-gauge readings, or within 4 to 6 per cent. One feature must be carefully considered in applying secondary stresses such as these, that is, that they usually reach a maximum near the panel points, and are not necessarily co-existent with a maximum compressive stress due to the flexure of a long column.

The general results of the strain-gauge readings seem to indicate that the stress in built tension members is greatest toward the center and the stress in built compression members is least toward the center of the section, which emphasizes the method used on the compression members of the Hell Gate Arch to make them take stress at the center first, and distribute it to the outsides or flanges.

The fact is also demonstrated that there is a better distribution under heavy stress, than for light stresses, and this was emphasized in many of the readings on the Niagara Cantilever.

The distribution of stress in the eye-bar chords of the Niagara Cantilever was determined by reading with the Berry strain gauge and was found to be better under heavy total stress than with light total stress. Table 2 illustrates this for the light loads *A* and *B*, and the heavy load *G*, in the top chord $U_8\ U_9$, composed of fourteen eye-bars. The load *A* consisted of one 188-ton locomotive followed by twenty cars weighing 2 740 lb. per lin. ft., with only the train load

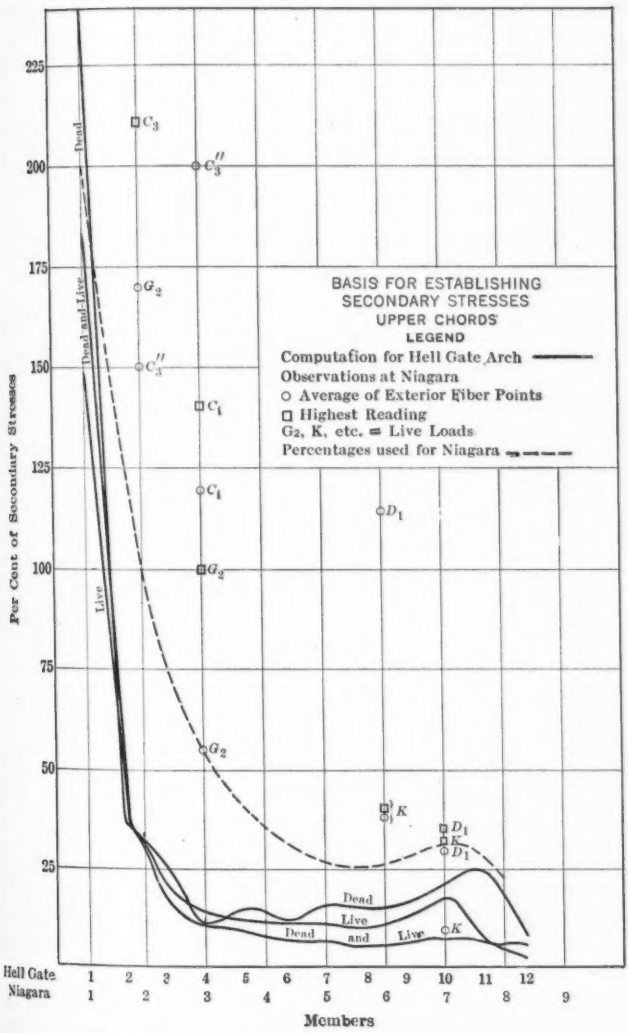

FIG. 7.—SECONDARY STRESSES IN NIAGARA ARCH AND HELL GATE ARCH COMPARED.

on the bridge; while Load *B* was the same train, with the locomotive on the suspended span and the train covering the cantilever and anchor arms. Load *G* was a 167-ton locomotive and six loaded cars weighing practically the same as for Loads *A* and *B*, but with the locomotive on the suspended span and the train load on the cantilever arm and suspended span, so located as to give maximum stresses in the bars of U_8 U_9, which was the tower panel of the top chord. The unit stresses for Loads *A* and *B* ranged from 300 to 1 300 lb. per sq. in., with an average of 700. The unit stresses for Load *G* ranged only from 2 300 to 3 300 lb. per sq. in., with an average of 2 800.

A careful study of the distribution of stress over the cross-section of either compression or tension members shows how little the supposed perfection of designs is realized in practice, both as to correctness of stresses and distribution. The stress measurements made at the same time on another structure, where the stringers rested on top of the floor-beams and were supposed to slide, disclosed the fact that one angle of a floor-beam flange was undergoing compression, while the other was in tension. The results obtained on the Niagara Arch were utilized only to the extent necessary for the re-designing of the structure, but it seems to be certain that comprised within the readings made there are the germs for many rectifications of the methods of calculation and design of large structures, and it is to be hoped that the results of this work will form the basis for future extensive readings on this arch.

Test Loads.

The test loads used by Mr. Roebling on the Suspension Bridge in 1855 have already been described, and from this 326-ton total load to the 1 670-ton load used by Mr. L. L. Buck on the arch span a great advance was marked. The 90-ton locomotives and 52.5-ton cars used to make up the test load, however, indicated that the assumed live load used in designing the new arch bridge was not taken heavy enough, and nothing less than Cooper's E-40 should have been adopted as it was presumably being used by some roads at about this time.

When trains were assembled for the 1918 strain-gauge readings, no difficulty was found in getting locomotives and cars nearly as heavy as E-50 loading, and no particular trouble would have been experienced in assembling trains fully equal to or heavier than E-50. The test trains, used over a period of nearly two months, were twenty-five in number and varied in average weight from 4 250 to 4 880 lb. per lin. ft. The weight of the cars alone varied from 3 840 to 4 320 lb. per lin. ft. Many cars passing over the bridge indicated also that a train load of 5 000 lb. per lin. ft. could easily be assembled, and would be considerably exceeded by actual trains before many years.

The test trains were located on the bridge during the strain-gauge readings, as indicated in the typical diagram, Fig. 8. The locations corresponded closely to positions for maximum stress in various members, as determined from a study of the influence diagrams. The length of the trains was also determined for giving maximum stresses for various members, in the locations fixed for the trains. The shorter trains consisted of one locomotive and four cars; the second of one locomotive and seven cars; the third of two locomotives and seven cars; the fourth of one locomotive and sixteen cars; and the longest of two locomotives with fourteen cars. The locomotives ranged in weight from 177 tons and 61 ft. 5 in. long, to 220.9 tons and 72 ft. 3 in. long. The heaviest locomotive likely to cross the arch is shown in Fig. 9. The cars were mainly steel hopper-bottom gondolas, 33 ft. 6 in. long, weighing empty about 18 tons, and loaded about 70 tons. There were a few larger cars, 42 ft. 6 in. long, weighing empty about 26 tons, and loaded about 100 tons. The trains used during the entire two months, however, were of an extremely uniform character, thus tending to great uniformity in the strain-gauge readings and increased accuracy. Practically no change was found in the strain-gauge read-

LOCATION OF TRAINS FOR STRAIN GAGE READINGS.

FIG. 8.

ings on the arch members whether the first, second, or third driver was located at a panel point.

Strain Gauges.

The greater part of the work of measuring stresses was done by the use of the well-known Berry strain gauge, using the 8-in. gauge for secondary stress work, and the 20-in. gauge for primary stresses. These instruments (Fig. 10) have the side strips made of "Invar" metal, the coefficient of expansion of which is only about one-twenty-eighth that of carbon steel, and the handling during use does not seriously affect the accuracy of the readings. One end has a fixed conical steel point, and the other end a movable conical steel point attached to a bell-crank lever. The long arm of this is attached to the spindle of an Ames gauge dial, and the lever has a multiplication of five times, so that while readings are made directly to 0.0002 in., they may be estimated to 0.00002 in.

All the instruments were carefully calibrated to determine their error, by the use of a standard micrometer screw, and all three Berry instruments were found to read slightly high, one 3%, one 3½%, and the greatest error was 4% on the third gauge. These errors were of course constant, and as they were far within the degree of accuracy desired, no correction for this has been made in the results as given in the tables.

The Howard gauge (Fig. 10) used on the Hell Gate Bridge was kindly

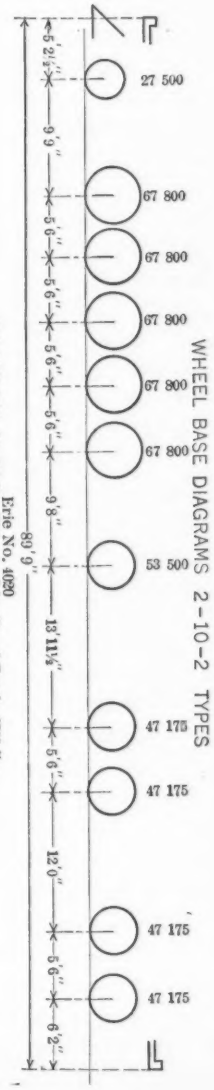

Fig. 9.—Heaviest Erie Railway Locomotive Allowable Over Niagara Arch.

loaned by Gustav Lindenthal, M. Am. Soc. C. E., for the purpose of making some comparative readings to determine the respective accuracy of the Berry, the Howard, and the Fuller-West instrument described in the following paragraph. The Howard gauge has one fixed and one movable conical steel point, the movable one having a horizontal sliding movement and being attached to a rod sliding in the tube which carries the fixed point. The distance between the two points is read by a micrometer contact screw at the end of the tube next to the movable point, and reads to 0.0001 in. There are two milled heads with a spring ratchet between them, which slips where contact is made. The inside milled head may be used, the operator depending on the sense of touch for the contact, or the ratchet outside head may be used. This instrument, not being of Invar metal is covered with leather for protection from heat in handling.

The Howard gauge obviously cannot be used except for static load readings, and while the Berry instrument was used with moving loads and for impact readings, the excessive vibration of the needle of the Ames dial made it difficult for the observer to get accurate readings of the maximum stress at all times, and, therefore, many check readings were required. This led A. H. Fuller, M. Am. Soc. C. E., to an investigation of the "Last Word" dial, made in Cleveland, Ohio, and to the construction of a much more reliable instrument, using this dial, by Mechanician West, of Lafayette College, embodying Professor Fuller's ideas and some suggestions from the writer. This instrument, called the "Fuller-West", is shown in Fig. 10 (the two lower figures), and is provided with fibroid handles to obviate trouble from change of temperature in handling. The joint of the movable point lever is a double cone pivot and much more accurate readings of moving load stresses can be made, and for static stresses it has been found to be more accurate than the Berry, or, in other words, where from eight to ten readings were made on a point with the Berry, a less number and one check reading with the Fuller-West instrument gave just as reliable results.

The accessory instruments are practically the same in all cases, so only those used in the Niagara Arch readings and for the stress readings made by the writer and his assistants on the Michigan Central Niagara Cantilever, will be briefly described, those for the Howard instrument having been fully described in the paper by D. B. Stein-

man, M. Am. Soc. C. E., entitled "Stress Measurements on the Hell Gate Arch Bridge".*

Standard Bars.—Two bars were made from pieces of ¾-in. gas pipe, long enough to allow caps to be screwed on to the ends and not interfere with the gauge points 20 in. apart. The caps were screwed on tight and were then ground down flat on one side to give a flat base to rest upon. In the center of each a slot was cut on the opposite side and a thermometer placed inside where it could easily be read. These standard bars were marked *A* and *B*.

In making observations a reading with the gauge was made on the standard bar, a group of points on members read, and then a check reading was made on the standard bar. The thermometer was read and recorded each time the standard bar was read.

Corrections for Temperature.—These were made from readings of special Fahrenheit thermometers which had been calibrated by comparison with a standard laboratory thermometer. The thermometers, twelve in number, were fastened in close contact to members of the bridge and the bulbs bedded in putty to protect them from the air. The locations were changed as the work progressed. It was not considered necessary to have a thermometer on each bar or member when it was being read for stress, but the temperatures were read at the same hour for members similarly located. Very large differences, up to 27°, were found on opposite sides of a member—in the sun or away from it. The corrections for temperature were made by taking the coefficient of expansion of the steel in the bridge as 0.0000065. All the thermometers were kept in the shade.

Members Read for Stress.

The members read for stress are shown by the heavy lines in Fig. 11. The members of the northeast quarter of the arch, down stream on the American end, were read most extensively, as that was more shaded from the sun. Members in the other quarters of the arch were read in sufficient number to give a check on this northeast quarter.

Gauge Points.—These were located on the upper part of the arch so as to be easily reached from the highway deck, and by means of low staging or ladders. The points for secondary stress were located near the main top gussets and in large enough numbers to obtain results

* *Transactions*, Am. Soc. C. E., Vol. LXXXII (1918), p. 1040.

for both longitudinal and transverse secondary stresses. Points were located on Post U_2 L_2 at two elevations below the highway deck, and, for the arched chord, they were located inside the chord members. The location of the temporary and permanent gauge points was recorded in tabular form.

Spots about 1½ in. in diameter were cleaned of paint and rust and placed either 8 in. or 20 in. apart as needed. The holes for the "points" were drilled with a Yankee drill about $\frac{1}{10}$ in. deep, and with a No. 56 drill. The burr was removed by a flat-angle countersink and finished by rubbing with a center punch. One hole of each pair was finished before the other was marked, by using a bar with center punches spaced 8 in. apart. The holes were protected when not in use by filling them with vaseline.

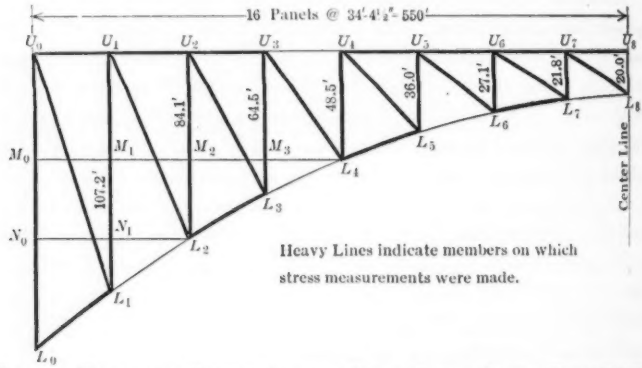

FIG. 11.—MEMBERS OF NIAGARA ARCH TO WHICH STRAIN GAUGES WERE APPLIED.

Permanent Gauge Points.—These were placed on members, as indicated in a list in the Company files, so that readings on such members could be checked up for different loadings at any future time. These points were set in the bottom of ½-in. holes ¼ in. deep, which were tapped and provided with cap-screws having a lead washer under the heads. The holes were filled with vaseline before the cap-screws were put in place.

Modulus of Elasticity.—The modulus of the steel in the bridge is the basis on which the strain-gauge readings have been reduced, and this is undoubtedly 29 000 000 lb. per sq. in. The character of the material was specified to be steel having a strength of from 60 000 to

68 000 lb. per sq. in. and an elastic limit of at least 33 000 lb. per sq. in. It should be noted, however, that the steel was really only of 30 000 lb. elastic limit, as the value determined by the drop of the beam of the testing machine was what is now termed the yield point, and 30 000 lb. has been used as the real value of the elastic limit.

The original tests of the material were obtained by the writer from R. W. Hunt and Company, of Pittsburgh, Pa., successors to G. W. G. Ferris and Company, the original inspectors of the steel in 1896 and 1897. These tests show the yield point to be as specified for the elastic limit, and, therefore, the elastic limit used in determining the proper load to put on the arch and approaches, has been taken at 30 000 lb.

The stress measurements or readings were recorded after the manner shown on the typical sheet, Table 3. In the first column, headed "Load", *D L* represents the static train load, and the letters refer to the standard

trains as indicated on Fig. 8, the details of each train being recorded in a record of "Test Loads". The date of the readings is given in the second column, and the exact hour in the third column. This enabled exact co-ordination of temperatures taken from sheets similar to Fig. 12. The first of the three columns headed "Temperature" gives the reading of the thermometers in the standard bars. Two standard bars were needed, one for each observation crew, and these were standardized one with the other, so that readings could be compared, and with duplicate bars kept in the fireproof vault, so that in case of loss they could be replaced. The second temperature column headed "Arch" contains the temperature as reduced from a large number of thermometers at various places on the structure, and represents the values used in making corrections for temperature stresses. The third temperature column gives that of the member read, and was

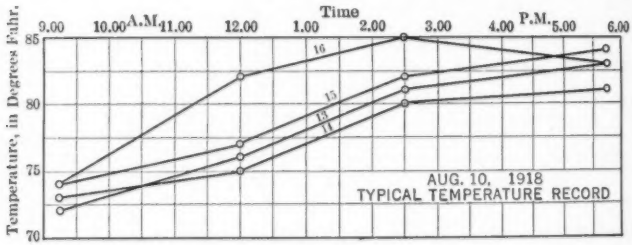

FIG. 12.

determined from thermometers fastened directly to the member or to one adjacent.

The results in the numbered columns are the strain-gauge dial units for the corresponding numbered point on the cross-section of the member in Table 4. The figures given are the averages of all the readings for that point, which were always two or more independent readings. Two temperature corrections were made for some of them, one, where there was a difference between the temperature of the member and the standard bar, and the other due to the temperature stresses in the arch. The large figures are the corrected ones, and the small ones the originals, thus making it possible to check the temperature corrections at any time.

The tables of live load stress measurements, Table 4 being typical, give the deformations in dial units which are direct deductions from

the dead and live load averages, and the stresses in pounds per square inch which have been computed from the deformations. An average of all the unit stresses in one member has been made and the area is given, thus making it possible readily to determine the total stress in the member.

About 400 gauge points were read on the members shown in heavy lines in Fig. 11, and upward of 5 000 individual and check readings made to establish the unit stresses. The readings were made in the cooler hours of each day so far as this was possible, but careful records of the temperatures were made as noted, and kept on about fifty diagrams similar to Fig. 12.

The comparisons made by calculating the stresses for certain members due to the test train used in the location for maximum stress, indicated that the results obtained by the strain-gauge readings were in error only from 4 to 6 per cent. This, of course, would not be true for members having very low unit stresses, as the unit stress must be of considerable amount to obtain an accurate result with the strain gauge; or, in other words, the error in the strain gauge is largely fixed in amount, and would, therefore, increase as a percentage the smaller the unit stress.

The practical uses for the strain gauge in actual construction or maintenance work on bridges were found to be many. Pending the substitution of stiff sway bracing instead of the rods in the 550-ft. arch span, it was necessary carefully to adjust all of them, some 96 in number, previous to the fall and winter of 1918; the former most careful adjustments by careful judgment were found to have put very little initial tension into some of the rods and too much into others. Some were found with 27 000 to 28 000 lb. per sq. in., or practically up to the elastic limit of the bars, which were of iron. They were all adjusted with the use of the strain gauge for an initial stress of 7 000 lb. per sq. in.

The movement of the segmental hinge rollers of the main arch at the skewbacks was so slight as not to be discernible by the eye, but by establishing gauge points, one on the upper steel casting and one on the lower, it was possible to detect movements with the strain gauge, due to moving trains, of from $\frac{1}{250}$ to $\frac{1}{1000}$ in., and readings at various temperatures established the total movement for extremes of temperature and loadings at practically $\frac{1}{10}$ in. This is quite small and extends over an

entire year, so that no fear is now entertained as to the rollers creeping, and although this has been corroborated by careful inspection extending over a year and a half, such rollers should have gearing similar to that used on the Ohio River Beaver Bridge. The addition of such gearing was first contemplated at Niagara, but hook indicators were attached to the side plates, which have a clearance of $\frac{1}{8}$ in. from the steel castings at 50° Fahr., and so if any creeping occurs it can be readily detected.

The reading of the dead load stress in the center top chord, U_7 U_8, of the arch span was accomplished in 1918 by the strain gauge, and by using a heavy toggle as described subsequently; and as this toggle was improved and duplicated for changing the center shims in 1919, there was available the toggle slabs and screws for other adjustments necessary in the reinforcement of the members. The method of reinforcing the intermediate and shore end posts of the 115-ft. approach spans, contemplated the placing of expensive falsework down to the rock banks of the Gorge, to relieve the posts of dead load while the reinforcing angles were being riveted to the old members. With an A-toggle (Figs. 13 and 14), abutting on the reinforced shelf at the bottom of each post and on steel blocks to distribute the pressure over the flange of the top chord, the dead load on the posts was relieved by screwing up the toggle until strain-gauge readings showed the posts to be free. This required from four to five dial units on the strain gauge. The toggle, when trains crossed, carried also a portion of the live load from the opposite track, as only two toggles were used at a time and placed on the posts of the trusses adjacent to the abandoned track. The fitting up bolts had to be loosened before the toggles were tightened, and drawn up again just before riveting began, to give proper adjustment.

The eight counters in the 115-ft. spans were replaced with U-counters having double the section, and the new rods were set with the strain gauge to have an initial tension of about 3 000 lb. per sq. in.

The greatest value of the strain gauge in the practical work on the arch revision was, of course, the checking up of the actual dead load stresses, which, on account of the introduction of the adjusting shims, did not agree with the theoretical stresses; an accurate checking of the distribution of stress over the cross-section of built tension and compression members; the checking of secondary stress; and the effect of impact at varying speeds.

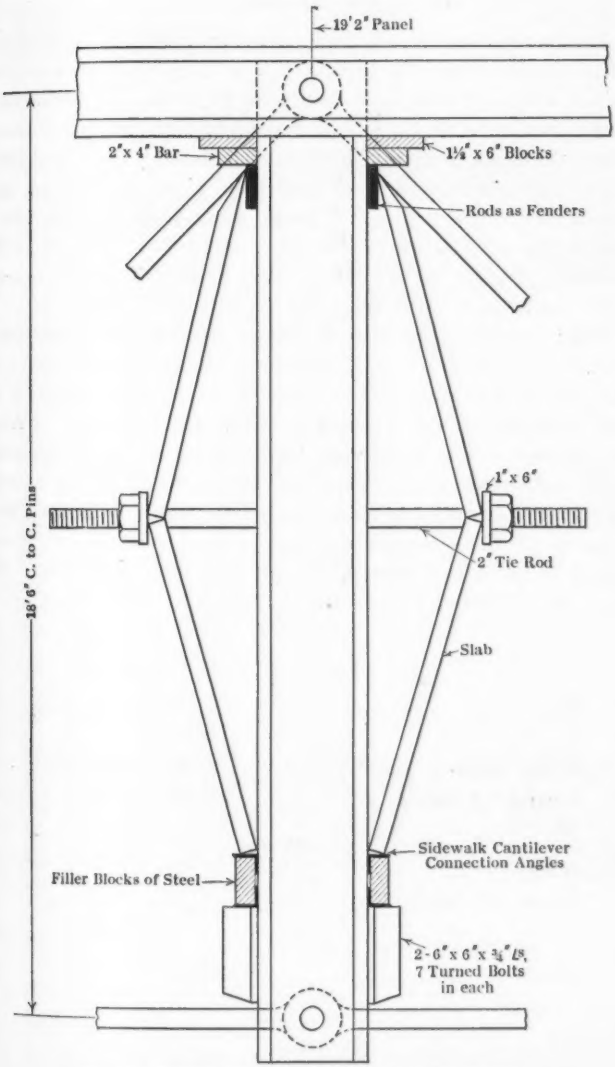

FIG. 13.—TOGGLE APPLIED TO POST OF 115-FT. TRUSS.

Unit Stresses.

The fact has been recognized for some time that for heavy, special, and long-span bridges, the Profession is no longer warranted in using the low values for unit stresses that are prevalent for less important shorter spans in which the secondary stress and closely accurate impact stresses have not been calculated or determined. Some authorities believe that where all stresses have been taken into account, unit stresses closely approaching the elastic limit should be used, with a loading that is quite sure not to be exceeded during the life of the structure, such as Cooper's E-90 loading or one similar to the composite loading proposed in this paper.

The fact remains, however, that there are still some uncertainties as to the uniformity of the elastic limit and the ultimate strength of materials, be they steel or steel alloys, as to the exact amount to be allowed for impact and vibration and as to the distribution of stress over the cross-section of the members, or stress transmission by means of pin and riveted joints. Therefore, for the Niagara Arch revision, after determining the minimum value of the elastic limit of the steel as shown by the somewhat extensive original tests thereof, it was decided to adopt unit stresses that are practically two-thirds of the elastic limit of 30 000 lb. per sq. in., as follows:

Tension	
Built truss members	20 000 lb. per sq. in.
Eye-bar members	22 000 " " " "
Girder flanges, net	18 000 " " " "
Laterals of shapes	26 000 " " " "
Shearing	
Girder webs	15 000 " " " "
Rivets and pins	15 000 " " " "
Bearing	
Rivets and pins	30 000 " " " "
Compression	
Girder flanges	$20\,000 - 200\,\frac{l}{b}$

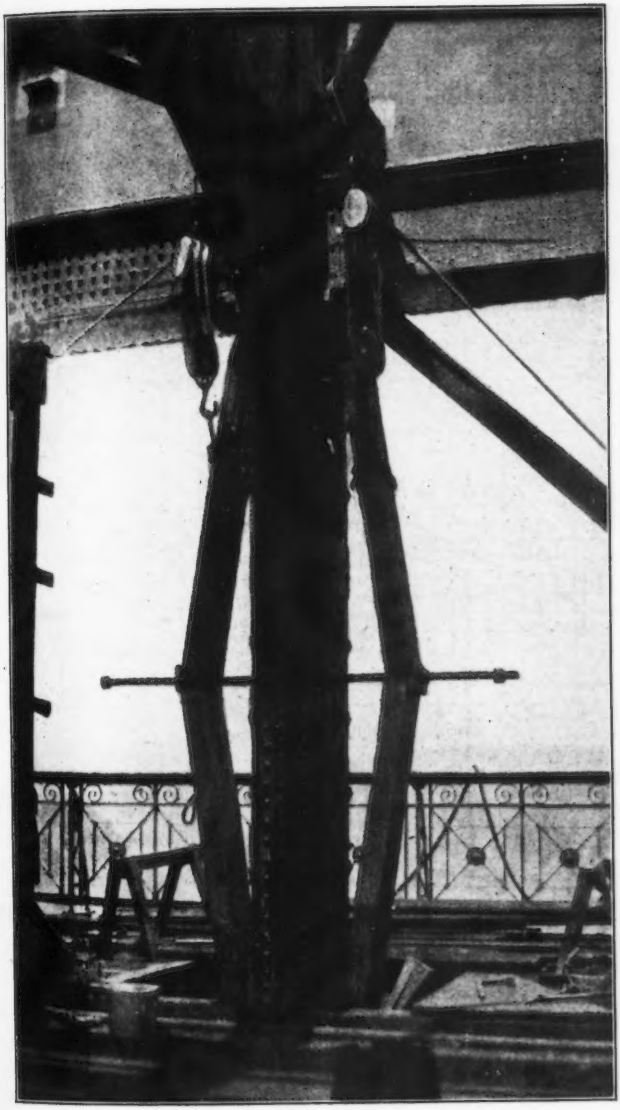

FIG. 14.—TOGGLE FOR RELIEVING DEAD LOAD STRESS IN POSTS OF 115-FT. SPANS.

Compression units for built chords and posts, were taken from diagrams similar to Fig. 15, using in each case the curves for an elastic limit of 30 000 lb.; while curves for nickel steel were established for use in future extensions of the bridge, where such material might be adopted. All these curves were established by plotting the values for column unit stresses as given by Mr. Lindenthal, in the specifications for the Hell Gate Arch, and then drawing the smooth curve which closely averaged them. The formula:

$$p = 23\,000 - 100\,\frac{l}{r}$$

represents closely one of these curves as shown in Fig. 15 and at the top

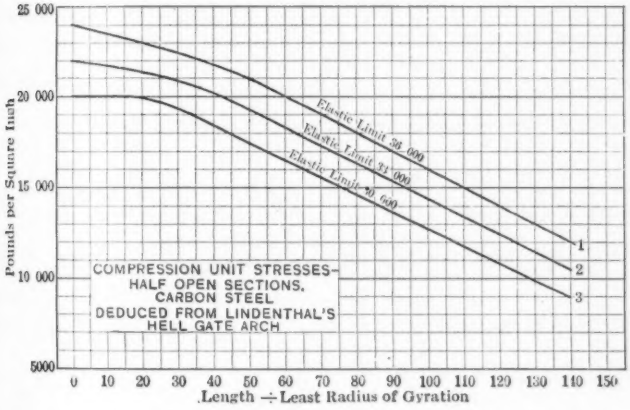

FIG. 15.

of Plate XXXVII, the maximum limit being fixed at 20 000 lb. per sq. in. and the maximum value of $\frac{l}{r}$ at 135.

The formula originally proposed for the Quebec Cantilever when all stresses, including secondaries and impact, were included, was:

$$p = 22\,000 - 88\,\frac{l}{r}$$

as shown in Plate XXXVII, which also shows the plotting of most of the principal column formulas, and which was made the basis of the adoption of the formula used for the Niagara work. The greatest number of these, in fact all those that are in general use, lie in a zone bounded

by $p = 12\,000 - 60\,\frac{l}{r}$ and $p = 18\,000 - 60\,\frac{l}{r}$, the average being the straight line formula, $p = 15\,000 - 60\,\frac{l}{r}$. The study by O. E. Hovey, M. Am. Soc. C. E., of the tests of columns made under the direction of the Special Committee on Steel Columns and Struts of the Society, shows that the ultimate strength of the light and heavy sections tested is represented by the respective formulas:

$$\text{Light columns, } p = 38\,000 - 70\,\frac{l}{r};$$

$$\text{Heavy columns, } p = 35\,000 - 72\,\frac{l}{r}.$$

These are plotted on Plate XXXVII for a safety factor of 2, and would indicate that all the present column formulas reduce unit stresses too fast for large values of $\frac{l}{r}$ and that for a two-thirds value of the average of the two Hovey formulas, we have practically:

$$p = 24\,000 - 47\,\frac{l}{r}$$

which gives much higher values proportionately than any of the ordinary formulas, especially for large values of $\frac{l}{r}$ or for very slender columns; and also indicates that the unit stresses used for columns in the Niagara revision were in comparison very conservative for the values of $\frac{l}{r}$ which existed.

The recent discussions before various technical societies and in the columns of the engineering journals indicate a strong preference for the retention of the straight line formula whenever a more logical value can thus be determined, and a careful study of the question shows that at least we should have a most careful review of all column tests made in the last thirty years, as the basis for a rational formula; and that it is preferable that more tests of columns of large size and careful design be made in a most painstaking and thorough manner. When such checked data are available, then unit stresses for columns can be tabulated once for all for safe end conditions, and no reason logically exists for caring what form the plotted line or curve may take, except that for convenience in memorizing and for use when tables are not at hand, some simple equation will still be desirable.

ERRATUM

For Plate XXXVII see page 1691.

Preliminary Methods of Calculation for 1918 Revision.

The following methods were applied in making calculations for the 1918 revision of the Niagara Bridge.

Arch Span.

Dead Load.—The dead load shall be taken at the value for the center top chord that will best assist the lowering of the stresses in the top chord, posts, and diagonals, and at the same time not overload the arch chord to an unsatisfactory degree. This will presumably be a value between 200 000 and 300 000 lb. for U_7 U_8 (300 000 lb. was finally adopted).

Live Load.—The live load shall be Cooper's E-60 trains on both tracks, and on account of the peculiar terminal nature of the service on this structure, they shall both be considered headed the same way.

Impact.—The impact shall be taken at 50% of the live load stress impact as determined by the old American Railway Engineering Association formula on the above amount of live load on each truss, based on tests of 1918 (or for a speed of 17 miles per hour).

The stresses shall be computed for the maximum position with both tracks loaded, and 90% of this value shall be used for the total stresses in both trusses, one-half of this to be taken for the stress on the members of one truss.

Wind and Lateral Stresses.—The wind and lateral stresses shall be shown separately, but shall be considered as combined and shall not be used in determining the final unit stresses unless the combined amount of such stress on any member exceeds 25% of the total of all the other stresses on the member; and then only the amount in excess of such 25% shall be used in determining the unit stress.

Floor-Beams and Stringers.—The stresses in the floor-beams and stringers shall be determined by using the full value of the impact as determined by the old A. R. E. A. formula (for E-60), on account of the very severe service wear of this part of the structure and excessive corrosion (50% used for E-70).

115-Ft. Approach Truss Spans.

The live load on the trusses of these spans shall be taken as 100% on both tracks, but the impact shall be taken at 50% of the old A. R. E. A. formula, as for the arch span.

The wind and lateral stresses shall be considered, as provided for the arch span, except in the case of the reinforcing for the intermediate posts, in which case the whole of the bending stress may be taken account of, if so elected or considered necessary on final analysis.

The impact on the floor-beams and stringers shall be considered in the same manner as for the same members of the arch (50% used for E-70).

Approach Girders and Columns.

The impact on the approach girders and columns shall be considered in the same manner as for the floor-beams and stringers of the arch span and of the approach truss spans (50% used for E-70).

Reinforcement of Floor System.

The railway floor-beams on the arch rest on the top chords and are riveted to them; but additional rivets, seven in number, were added at each end. Large curved brackets for sway bracing are riveted to the beams and to the vertical posts, extending down to the bottom of the highway floor-beams which are riveted between the brackets. This entire construction was figured as a rectangular frame, and it was found that it was unnecessary to reinforce the flanges of the beams for the E-70 loading, but it was found necessary to add 10 by ½-in. plates to the flanges of the brackets. The plates on the inside of the brackets were extended along the bottom flanges of the beams to provide enough rivets to take up the stress carried by the plate, and attached to the beam flange by an I-section of plates and angles.

The values of the horizontal thrust, H, were determined by the Greene method, applying the formula originally used in figuring the arch stresses. This is a very sensitive formula and great care was used in calculating the value for each panel load, and all the calculations were thoroughly checked, so that it is certain that no sensible error was made in this basic matter. This was regarded as particularly important, due to the fact that much doubt was expressed by those discussing the paper describing Mr. Buck's methods as used in 1896, as to the correctness of the value of H originally used.

Arch Stress Readjustment.

The very extensive investigation made by the writer, in preparing a discussion* of the paper on "Economics of Steel Arch Bridges", indicated that for such a structure as the 550-ft. Niagara Arch it would have been economical to have designed it as a three-hinged arch for dead load, but also to act as a two-hinged arch under live load. The fact that Mr. L. L. Buck had added a section to the curved chord equal to one-half the difference between the section required in a two-hinged and that for three-hinged arch, showed the advisability of determining in some manner the actual dead load stresses existing in the arch ribs after the introduction of the 1-in. shim for closure of the arch when the erection of the span was completed. This operation was partly described in the paper published in 1897, but, briefly, it may be stated that the

* Page 47.

ribs did not close at the center top chord joints by about ½ in. The arch was opened still further by the large shore toggles and a small adjusting toggle on each chord, so that a 1-in. shim was placed in each opening, which it was calculated would give the final 572 000-lb. stress in each chord as required for a true two-hinged arch. No way was provided at that time to measure the stress, and while it was at once evident that the small adjusting toggle would not have produced so much stress, it was later learned by the writer that the large shore toggle aided in producing a stress of 689 000 lb. in each chord, as measured on October 13th, 1918, for the north center chord, U_7 U_8, in the following manner:

The plates riveted on the center top chord webs for skewbacks in 1896 were reinforced for the load to be picked up by the new toggle by driving additional rivets in the front edge, and by bolting with 1-in. turned bolts, near the end a 4 by 1-in. bar at each point, to prevent the buckling up of the plate under pressure (Fig. 17). The adoption of a king-post toggle, such as was originally used, was out of the question owing to interference with the beams and bracing on the inside of the chords, and a heavy queen-post toggle was designed, as shown in Figs. 16 and 17, of sufficient strength to pick up a 400-ton load. This was supplemented by placing house-jacks inside the chords to counteract the transverse thrust at the skewback contact. The toggle, as modified slightly for actually changing the shim, is shown in Fig. 16.

Gauge points were placed on the chords between the center joint and the skewback points, so that when the toggle was screwed up, after cutting out all splice rivets on one side of the joint, this portion of the chord was free, even from its dead load stress, and the difference between the strain-gauge readings before and after the joint was opened gave the actual unit stress. Traffic was suspended during the time of operating the toggle but a light passenger train was allowed to use the opposite track before the toggle had been entirely slacked away.

The use of the toggle in 1918 for stress measurement indicated, from the bending of the heaviest wrenches at hand, that screws with more threads per inch should be substituted the next year for actually changing the shims. The use of wood blocking for keeping the toggle in line at the "hips" proved very unsatisfactory, and spacer bars with check nuts were used against the chords in 1919. Then, for safety,

lock nuts were provided outside the main adjusting nuts on one pair of rods in each of the two toggles, and special long nuts were provided for the other sets of rods for making the final turns. Screw-jacks were also placed opposite the hips inside the chord, to account for the thrust from the spacing bars.

When the stress had been read for $U_7\ U_8$ in 1918, a dead load stress sheet (Table 5) was prepared showing the stresses from dead load only in each member of the arch ribs, for zero stress in the center top chord, and for other values advancing by steps of 200 000 lb. for each column in the table. From this it was possible to determine that it would be out of the question to change the center shim to make the arch truly three-hinged under dead load, and it was decided to prepare the new stress sheet for a center top chord dead load stress of 300 000 lb., and on the completion of all stress computations, this proved to be the value adopted for final use.

The old toggle was remodeled, a second one was made for the other chord, and after careful preparation the shims were changed on October 1st, 1919. Operating platforms were built outside and inside both chords (Fig. 17), about 2 ft. below the bottom flanges, so as to facilitate the erection and operation of the toggles. The rivets were cut out of all splices on both chords, on all beams and bracing in any way tying the two halves of the ribs together, and 50% of the $\frac{15}{16}$-in. holes were filled with $\frac{7}{8}$-in. bolts with washers on both sides, and these were only loosely tightened so as to allow the joints to slide the necessary distance on the gussets, the outside splice plates being entirely removed to permit changing the shims. The stringer connections were cut loose at the eight points at the U_7 floor-beams, thinner filler plates placed, and the connections bolted, 1-in. turned bolts being used in the connections under the north track carrying trains.

During the changing of the shims highway traffic was not stopped, but at 8.00 A. M. railroad traffic was entirely suspended. Two hours were consumed in completing bolting operations and adjusting the toggles, but at 10.00 A. M. the tightening of the screws began. The superintendent blew a whistle and each of the sixteen nuts, one on each end of each rod, was given four turns, and when all were abreast this operation was repeated. Some delays occurred, but on the completion of twenty-six turns in less than two hours, the old shims were loosened and could be withdrawn with the fingers. After lunch they

were all removed and the new shims, about $\frac{3}{8}$ in. less in thickness, were placed, and on all adjustments being made, the nuts were slacked off five turns at a time, and by 4.00 P. M. the joints had all been bolted sufficiently to allow resumption of railway traffic. Not a mishap had occurred in completely jacking apart the top chords of the 550-ft. arch span, and in picking up with both toggles practically 700 tons. The adjustment of the center diagonals and the center sections of the bottom chord to the new stress conditions had been provided for by curving out the gussets between the diagonals and the center posts by means of a oxy-acetylene burning torch and by cutting out all the rivets in the connection at L_8 as far as possible with the south track out of commission; the number of rivets that were cut out was roughly 50 per cent.

The measurement of stresses in the toggles showed that at one time, near the maximum load, the small center slab was undergoing bending, due to the eccentric application of the load on the end. This slab was blocked and no trouble resulted.

The stresses, as read on October 1st, were calculated that evening and showed a wide variation from the 300 000 lb. total desired in each chord, as follows:

North chord	98 000 lb.
South chord	200 000 lb.

The check made of the old stress of 689 000 lb., as measured in 1918, showed for the north chord 715 000 lb. and for the south chord 688 900 lb., being only 3.8% larger for the north chord, presumably due to stress carried in 1918 by the four lines of stringers which were tightly fitted, and a practically identical reading for the south chord.

The large number of heavy freight trains that had been held up while the work was in progress, were run over the north track during the ensuing 16 hours, until final readings could be made the next morning, October 2d. Then the resulting total stress after full readjustment was as follows, adding for the stress that would be caused by the placing of the ties and rails of the south track which was just ready for laying:

North chord	288 000 lb.
Stress from south track	14 000 lb.
Total stress	302 100 lb.

South chord	255 000 lb.
Stress from south track	38 900 lb.
Total stress	293 900 lb.

These stresses may be considered as practically exact, that for the north chord being within 1% of the desired value, and that for the south chord within 2 per cent. This close agreement resulted from the reading of the dead load stress in 1918, the very careful calipering of the old shims, and the many check strain-gauge readings. Owing to the fact that the thickness of the new shims was reduced in exact proportion from that of the old shims, the distribution over the cross-section of the four chord sections, U_7 U_8, remains practically the same as before the change.

Stress Sheet.

The recorded data on the former stress computations were very meager, consisting of the stress sheet* of the paper by Mr. L. L. Buck, a blue-print diagram of lateral and sway stresses, together with a record of the calculation for ΣH for the arch ribs.

The original total stresses included simply live load, dead load, and temperature stresses, no account being taken of secondary stresses or impact. The unit stresses assumed were, for the diagonals in tension, dead load 20 000 lb. per sq. in., and live load 10 000 lb. per sq. in.; for compression in the top chords, dead load 18 000 lb. per sq. in., and live load

$$\frac{9\,000}{1 + \dfrac{l^2}{30\,000\,r^2}};$$

for posts and diagonals in compression, dead load 16 500 lb. per sq. in., and live load

$$\frac{9\,000}{1 + \dfrac{l^2}{30\,000\,r^2}}.$$

The resulting unit stresses on the sectional areas adopted were as follows:

Top chords	3 650 to 12 700 lb.
Bottom chords	11 500 to 12 800 lb.
Diagonals (tension)	10 600 to 12 600 lb.
Vertical posts	5 350 to 11 100 lb.

* *Transactions*, Am. Soc. C. E., Vol. XL (1898), p. 149, Plate XII.

The new stress sheet, Table 6, consists of a column for each class of stress, and by every method for each class which it was desired to have, either for comparison or final combination. The result was a sheet of thirty columns, affording much data in the way of valuable comparison and enlightenment for obtaining final maximum and minimum stresses. The first eight columns are all dead load or non-dynamic stresses, including dead load, temperature, snow and wind load stresses; the next nine columns are for train live load stresses both direct and reverse, together with impact by the Schneider formula, the Lindenthal formula, the proposed new American Railway Engineering Association formula added later, and from the Niagara impact readings with the strain gauge. Attention is called to the low values given by the proposed new A. R. E. A. formula, and their comparison with the Niagara readings, which are not necessarily a corroboration of the correctness of the proposed new A. R. E. A. formula. The comparison of the Schneider and Lindenthal values shows that there is not a wide divergence on the average for the compression members, but indicates much higher values by the Lindenthal formula for the tension diagonals, as would seem logical from the viewpoint of safety, although not corroborated by the Niagara strain-gauge results. The careful study of all the values would indicate that the results obtained by the proposed new A. R. E. A. formula are very low for the usual average speeds over main-line bridges. The fixing of the critical speed would therefore seem to be the first necessity of a perfect formula, and, secondly, the coefficient or function herein developed to be introduced for variation in speed—these two factors being intimately correlated.

The next seven columns of the stress sheet cover the highway live load, direct and reverse; the lateral live load; and the secondary stress percentage, with the equivalent in thousands of pounds, the percentages being 10% flat for the bottom chords, from 20 to 200% for the top chords, from 15 to 45% for diagonals, and from 30 to 60% for the vertical posts.

The last six columns comprise the total stresses as combined from the various stresses, giving both minimum and maximum stresses, and 50% of the reverse minimum. The last two columns give the allowable unit stresses as fixed for the revision of the structure and the maximum resulting from the combination of the co-existing actual stresses.

Although the posts from U_1 L_1 to U_4 L_4 show an excess, a consideration of the secondary stress strain-gauge readings shows them to be within the limits set for direct compressive stress; furthermore, the effective length is much reduced by the highway floor-beams and stringers connecting at the highway level.

Methods of Reinforcing.

The reinforcement of the posts of the 115-ft. span, and of the viaduct, consisted of two angles back to back on each web, but in some cases a filler plate was used. The holes in these plates and angles matched the old rivet spacing in the webs as far as it extended, and when the new material had been bolted in place by a few bolts, the additional holes were drilled through the webs with high-speed air drills. Every other hole was bolted before riveting, and the bolts tightened before riveting but after the dead load had been relieved, either by the toggle on the 115-ft. span posts as already described, or by shores and jacks to carry the dead and live load for the approach columns.

The old cover-plates on the approach girders, the stringers, and the floor-beams of the spans were cut loose by cutting out the rivets by hand, except for the old rusted top plates which were to be thrown away and could stand the heat from a cutting torch. These rivet heads were burned off at the rate of 600 to 700 per day, or equal to the number removed by four hand gangs, and the rivets were then backed out by hand. The new top cover-plates were countersunk so as to leave a smooth surface to receive the 14-in. maple risers, but experience indicates the desirability of countersinking top flange rivets in all railway bridge stringers or deck girders, so that ties need not be bored or notched for rivet heads. All new plates were riveted up after removing the dead load stress by shoring up from below with 8 by 8-in. shores and wedges for the stringers on the spans, one for each stringer; but two 12 by 12-in. shores were used under each of the approach girders, which were from 40 to 52 ft. in length.

The reinforcing plates on the curved brackets were clamped in place, the holes drilled through the old flange and the riveting done without any shoring, as there was practically no dead load stress to be considered. The new counters in the 115-ft. spans were $1\frac{3}{16}$-in. square **U**-bars, or two bars replacing one of the same size, which would

have been stressed to more than 40 000 lb. under E-60 loading. The old loop eyes were burned off on each side of the pin by using a torch, so that the old counters were easily removed, after previously putting in four strands of wire rope, tightened by turnbuckles to carry the counter stress until the new rods were in place. The short U-bars were then slipped around the top and bottom pins, the straight sections connected up, and tightened with the four turnbuckles to an initial stress of 3 000 lb. per sq. in., as shown by strain-gauge readings.

The viaduct posts had originally been built with bases 40 by 43 in., resting on pedestal blocks of stone 5 by 5 by 2 ft., entirely above the pavement. This had become an obstruction to traffic of a very serious nature, and as two of the stone pedestals had become cracked, it was decided to replace the two nearest each entrance to the highway floor with extensions of the steel post section to below pavement level, with a flaring base to distribute the pressure over the concrete footing. These bases were built up of channels and plates, as it was impossible to obtain steel castings within any reasonable time. They were fully spliced to the columns after the old base plates and connections had been burned off, the pockets having been filled with water-proof concrete directly against the metal. The space between the bases and the pavement was filled with concrete in concave curves to ward off the wheels of vehicles. The additional gain in roadway width was about 4 ft. The post reinforcing was increased to provide for the increased value of $\frac{l}{r}$.

Sway Bracing.

The new diagonal sway bracing (Fig. 18), in the bents, U_0L_0, U_2L_2, U_4L_4, is composed of two 12-in. channels for each member, laced with 3 by 3 by $\frac{3}{8}$-in. angles double-riveted, and having a stiffening angle on each tie-plate. The old rods were not removed until four wire ropes with turnbuckles had been placed to take the stress, one vertical panel being replaced at a time, and it was required that a panel be finished the day it was begun, as a measure of safety. The connections to the arch ribs was made by means of the large gussets connecting generally to old holes with very few new ones to drill. The posts were also diaphragmed opposite the bottom gussets. The center gussets were made large enough and holes were provided for connecting struts that will be necessary when two more ribs are

added to the arch, and then the end connections can be increased in strength by placing the rivets in double shear. When new ribs are added, stiff bracing will be placed in the alternate bents as well. The bracing of the end bents, U_0L_0, has connected to it steel stairways as shown by Fig. 18, the outside stringer being a single channel, and the steps formed of two rods with pipe separators. The rise makes the stairways very easy to climb and they are a distinct advantage in ease of access for making repairs to the bridge.

The two vibration struts in each bent, U_1L_1, and one in each bent, U_3L_3, as shown in Fig. 18, are 10 ft. deep, with two 5 by 3 by $\frac{3}{8}$-in. angle flanges, and $4\frac{1}{2}$ by 3 by $\frac{3}{8}$-in. angle web members. They are purely for counteracting vibration, and are connected or steadied by angle lugs at the middle pin of the sway rods. They, as well as the diagonals, serve the purpose perfectly, and the side sway and swing of the bridge which was so objectionable has been practically eliminated, besides making the arch perfectly safe against vibration from heavy trains.

New Grade Line.

The grade line of the arch was originally made to conform to the large camber of the old suspension bridge, as a means of erecting the arch around the stiffening trusses of the latter without stopping traffic. This made a sag in the grade of practically 18 in. between the center of the arch span and the New York Central Railroad crossing on the American shore, or practically at the shore end of the 115-ft. span. The heavy grade incidental to this made it necessary for the heavier freight trains to cross the bridge at speeds of from 20 to 30 miles per hour, which were considered unsafe for a bridge of this character—so high and directly above the Rapids. Therefore, it was decided to remove this sag by means of steel risers on top of the stringers, which also were made to serve as the new top flange of these stringers on the American half of the arch and on the 115-ft. span. The rise in the first panel next to the center of the arch was made entirely in the 14-in. maple risers of the new floor.

The risers in the next two panels consist of four angles telescoped, and, for the remainder of the arch, of four angles and a web-plate, with stiffeners every 4 ft., all risers being tapered to conform to the new grade. The risers on the 115-ft. span are of Bethlehem H-beams, 10 and 12 in. deep, with end stiffeners only.

FIG. 18.—NEW SWAY AND VIBRATION BRACING.

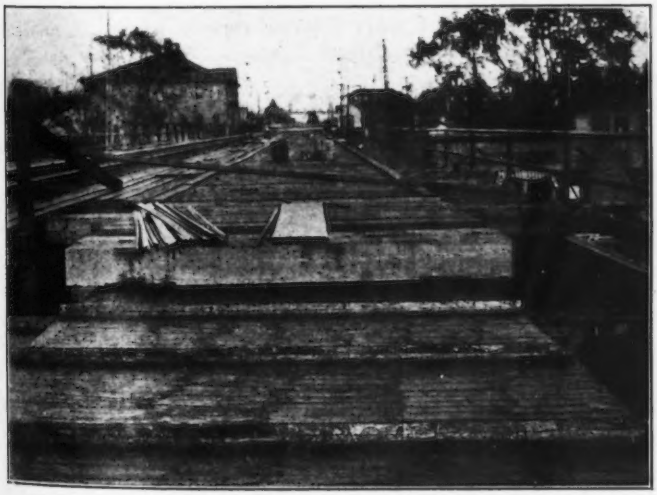

FIG. 19.—COPPER-STEEL RAILWAY PROTECTION FLOOR, SHOWING TIE RISERS AND COVER STRIPS.

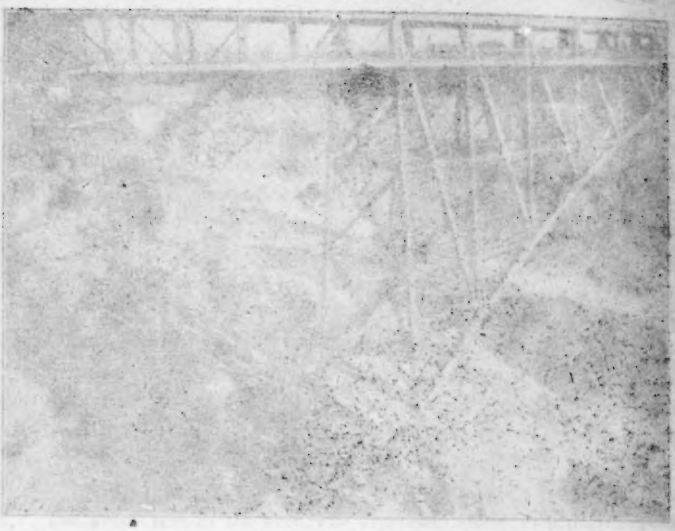

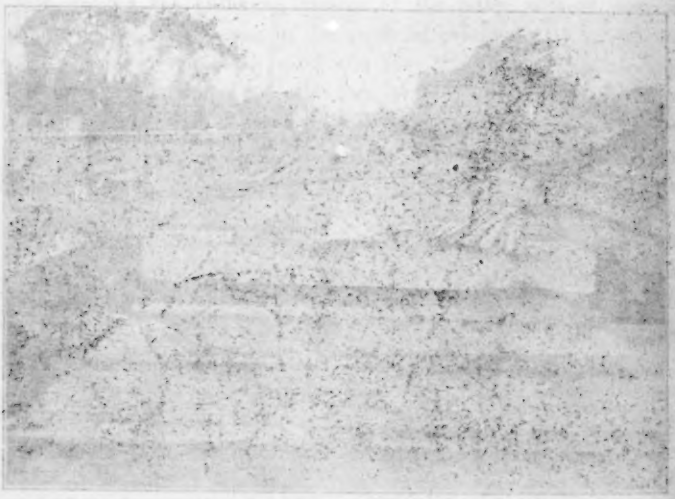

The American approach was jacked up bodily 12 in., and cast-steel bases were inserted between the steel bases of the columns and the masonry. This jacking was done for all three of the American 48 ft. 6-in. double-track spans, during the two hours when the trains were stopped. Bents of 12 by 12-in. timbers had been previously placed, and eight 60-ton jacks on shores, two at each point, were used to raise the 300 tons. The jacking began on a whistle signal, and all points were raised and blocked 1 in. When all were abreast, a second signal was given for raising the second inch. Marks had been made to watch for creeping, but none occurred. With the new castings and sheet lead in place, the anchor-bolts were temporarily placed, the new north track was connected, and trains were allowed to cross.

New Railway Floor.

The old railway deck had been placed originally with galvanized strips between the ties, small wooden side gutters, and 2½-in. galvanized downspouts to protect the steelwork from salt water drip and the highway traffic from water coming through from above. This proved unsatisfactory, and, later, wooden strips with a groove for a gutter were used between the ties. This was apparently a passable protection, but in the dry weather period a great deal of leakage made it unpleasant for the highway traffic. While making the 1918 inspection, the condition of the top flanges and angle laterals between them, of the stringers, floor-beams, and girders was investigated to ascertain the extent of the salt-water corrosion from refrigerator car drippings. The only places that could be reached were the small spaces between the ties, and below the small, wooden gutter strips. It was found that the corroded metal could easily be pried off in flakes from $\frac{1}{4}$ to $\frac{3}{4}$ in. thick. Later, by using a rolling staging, spots were scraped on each top flange at frequent intervals and it was found that plates and angles originally from $\frac{3}{4}$ to $\frac{1}{2}$ in. thick, were wasted away on an average of 50%, or in extreme cases only $\frac{1}{16}$ to $\frac{1}{8}$ in. thickness remained.

Studies were at once begun to find some type of floor that would be a practically perfect protection against this salt water and also the blow-off water from locomotive boilers. There was found to have been no real attempt by any one to solve the problem, except the endeavor of the American Railway Engineering Association to have

efficient drip tanks placed in refrigerator cars, and the use in some cases of heavy concrete troughs to carry ballast and tracks.

The latter solution is represented by the heavy reinforced concrete floor as designed and used by Charles F. Loweth, M. Am. Soc. C. E., Chief Engineer of the Chicago, Milwaukee and St. Paul Railway. This is a splendid type of construction, but as it weighs 3 400 lb. per lin. ft. of track, could not be considered for use on the Arch Bridge. One of the lightest floors of this type is in use by the Buffalo, Rochester and Pittsburgh Railway, and was only slightly too heavy to be considered, weighing 2 200 lb. per lin. ft. of single track. The design shown in cross-section in Fig. 20 was within the weight limit desired, and a test section was made with the cement gun. Tested with its own

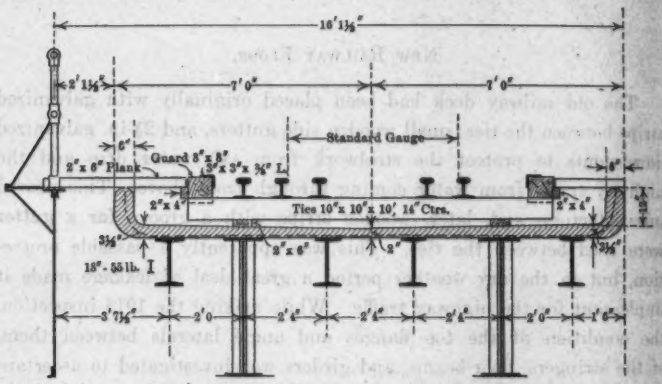

FIG. 20.—LIGHT CONCRETE FLOOR AS TESTED.

weight over a span of 13 ft. on 12-in. blocking, it sagged about 6 in. and developed hair cracks. It could be tetered up and down 6 in. with one's foot and return to its original sagged elevation, and so far as tests indicated would be satisfactory for the short spans between stringers and new jack stringers. It was discarded mainly on account of the certainty that it would shatter under traffic. The idea, with certain evident modifications, is worthy of a trial on some new bridge.

The design, which was finally approved from an engineering standpoint, was a ⅜-in. flat steel plate protection with proper protective coating. Furthermore, this made it possible to carry the water away by side downspouts, but when the cost was considered, and the cost of maintenance as well, some lighter plate floor was found desirable.

The suggestion of the use of $\frac{1}{8}$-in. special iron was at once rejected, and a plan for $\frac{3}{16}$-in. special iron floor was prepared for bids. The labor and shop conditions were finally responsible for the use of this $\frac{1}{16}$-in. floor, shown in detail in Fig. 21, which could be largely fabri-

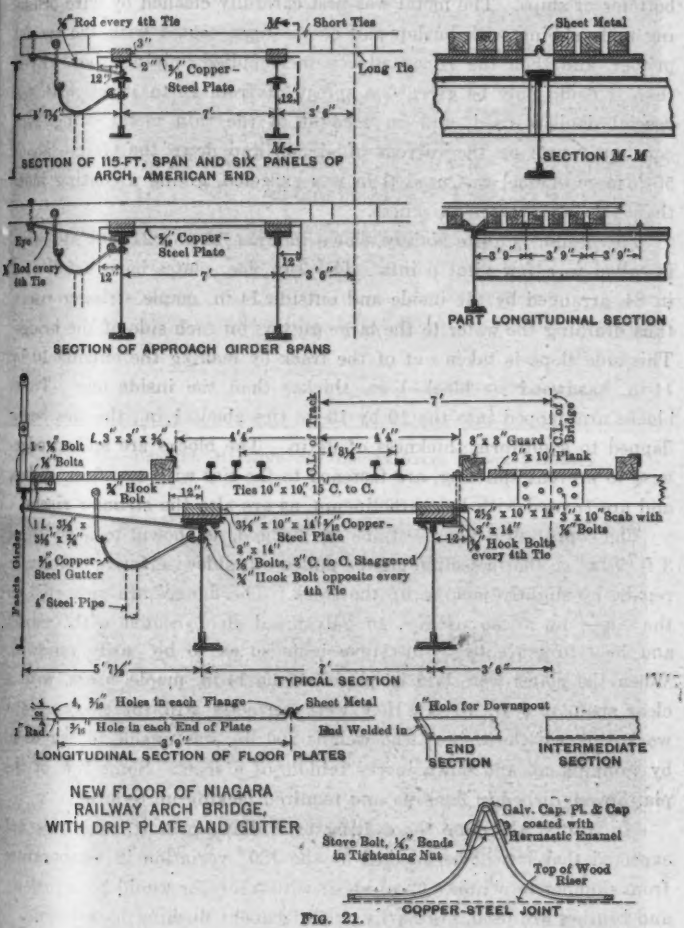

FIG. 21.

cated in the field, and easily maintained and repaired by ordinary workmen. The bids were received both on the special iron and copper steel, and the latter was adopted on account of a material saving. No

idea was entertained, however, that any metal as usually painted would last long when undergoing the corrosive action of the salt-water brine; therefore, the copper steel was coated, after fabrication and laying, with Hermastic enamel of a grade such as is used for the double bottoms of ships. The metal was first carefully cleaned by wire brushing and rubbing with burlap and coarse rags, coated with the special primer, and then the Hermastic enamel applied "piping" hot. Even then it could only be given one spread of from 12 to 18 in. with the special daubers used, and on account of the thin metal being kept constantly cool by the current of air up and down the Gorge, about 50% more enamel was used than was expected, giving a coating more than $\frac{1}{4}$ in. in average thickness.

The design is quite plainly shown in Figs. 19 and 21, but attention is called to a few vital points. The 9-ft. floor-plates have a fall of 1 in 84, arranged by the inside and outside 14-in. maple stringer risers, thus draining the water to the large gutters on each side of the bridge. This side slope is taken out of the track by making the outside 10 by 14-in. hardwood tie block 1 in. thicker than the inside one. These blocks are dapped into the 10 by 10-in. ties about $\frac{1}{2}$ in., the ties being dapped to a uniform thickness of $9\frac{1}{2}$ in. The blocks are spiked edgewise to prevent splitting, are fastened to the ties with two 6-in. spikes, and are treated with hot carbolineum, as are also the stringer risers.

The copper-steel floor sections are flanged, as shown, to a width of 3 ft. 9 in., so that a section can be pulled out sidewise for re-coating or repair, by slightly jacking up the track. The flanges are protected on the edges by a cap of No. 16 galvanized steel, coated with enamel and held in place by $\frac{5}{16}$-in. stove bolts so as to be easily renewed. When the plates were laid in place on the 14-in. maple risers, with a clear span of 5 ft. 10 in., they were perfectly stiff for carrying the workmen, and the writer, who weighs 200 lb., was unable to sag them by jumping up and down in the middle of a sheet. Some few of the plates were dished in flanging and required jacking up to level.

No injury was done the coating by walking over it, and it is not expected that it will be affected by the 120° variation in temperature from summer to winter. Cleaning it with a scraper would be injurious, and brushes are used, ordinarily, with frequent flushing by a hose.

The flanging of the plates was done at the bridge by the home-made bending machine shown in Fig. 22. This was constructed from old 12 by 12-in. timbers drift-bolted together with the edges of the jaw

FIG. 22.—BENDING MACHINE FOR COPPER-STEEL FLOOR PLATES.

FIG. 23.—SKEWBACK THRUST WALL AND ARMORED CASING, CANADIAN SIDE.

timbers protected by old angles and plates. The copper-steel plates were extraordinarily stiff, and the flanging timber was trussed by a hog rod as shown. This timber was operated by two oak levers about 10 ft. long and by lines running over snatch blocks to the nigger-heads of a hoist engine. The plates were clamped in the machine by the counterweighted timber, which in turn was clamped down by the two levers bound on the edges with strap iron, which turned down on to plates spiked to the timbers. The exact width of the plates was obtained by using gauge angles on the bed of the machine, and the exact angle of the bend was first found by trial, allowing for the spring of the plates. The machine was operated without trouble to bend about 600 plates, five men bending an average of about 50 to 60 plates per day of 8 hours. These plates under the tracks have wooden stop-waters of 3 by 3-in. carbolineum-coated timber, spiked to the under side of the ties so as to bear tightly against the inner ends of the floor-plates.

The gutters (Fig. 21) were formed into the desired cross-section by bending rolls at the shop, after being punched on the interior ends for lap splicing with ⅞-in. rivets, which were driven by air guns in the field. The ends were welded in the field with a welding torch, and the holes for the 4-in. downspouts were burned in the field with a torch.

The gutters have a fall of 6 in. for the girder spans, varying from 40 ft. to 52 ft. 3 in. for the 19 ft. 2-in. panels, and 4 in. for the arch panels of 34 ft. 4½ in. length. This is a slope of from 1 in 100 to 1 in 80, and gives quick drainage. The large size of the gutters was adopted in order to protect the highway deck near the sidewalks from splash and drip beyond the floor-plates.

The downspouts are of 4-in. steel pipe with screw joints, but attached to the gutter with flanges having oak filler gaskets soaked in linseed oil, and band-sawed to fit the curve of the gutter. All the downspouts are long enough to discharge below the bottom chords of the three spans, and are supported below by band clamps on the pipe and fastened to convenient lateral gussets.

The track is fastened down by hook-bolts to the inside stringers at every fourth tie, and anchored sidewise by the eye-bolt rods on the approach girders, and in the same manner on the spans, where the raised track is above the fascia girders. On the remainder of the spans the fascia girders have tie-rods to the stringers, as shown, with angle clips connecting every fourth tie to the top flange of the fascia girder.

The cost of repairs to make good the damages caused by salt water was over $30 000 and the cost of the copper-steel salt-water protection was about the same. These two items indicate how serious a problem is confronted in the matter of having refrigerator cars equipped with salt-water drip-tanks. These might be made very easily and economically by using large wooden boxes of matched flooring and lining them with thin sheet copper, well nailed in place to prevent its being stolen. These tanks cannot be emptied automatically, since they would be about as likely to discharge on a bridge as elsewhere; so they must be arranged for quick discharging, and yardmen must be trusted to keep them emptied.

The track as finished has a practically smooth surface and only about 0.1% grade. It belongs to and was laid by the railway company, lessees of the railway deck, and is of the best type of construction throughout, as was mutually agreed upon. The rails are 100 lb. per yd., of the A. R. E. A. section, with continuous bridge joints. The tie-plates, 7 by 10½ in., are of the Lundie type, especially large and heavy. The rails are laid with tight joints to prevent hammering and are provided with large expansion joints in each track of the Quebec Bridge type, at both of the ends of the bridge, to allow for approximately 5 in. of expansion, which is concentrated at the shore ends of the 115-ft. spans. Inside guard-rails of 100-lb. section are used, and an outside steel guard-rail of the same size spaced 5 ft. from the inside of the inside track rail to the inside of the guard. Borden tie-spacers are used between the ties, two lines to each track. The walkways are of 3 by 3-in. timbers laid ½ in. apart.

The old floor was very noisy during the passing of trains, but the new one, due to the maple risers and the Hermastic enamel, is very quiet and as nearly noiseless as is possible to build. Certainly, it is a demonstration that elevated railways of practically noiseless construction can be built. The cost of the high-class tracks alone was about $12.90 per lin. ft. of one track, and including the copper-steel floor complete about $27.50 per lin. ft. of one track. This would indicate that no bridge on account of extra cost need be constructed, leaving the upper metal work exposed to corrosion, and the floor system and bridge subject to destructive local impact increments, due to the desire for the possible financial saving that would result from the use of a less perfect track, and the lightest possible protection.

Highway Floor.

The new highway floor was built for a capacity of 2 130 lb. per lin. ft., on the trusses of the 115-ft. spans, and of 1 500 lb. per lin. ft. of bridge on the trusses of the arch span. The joists on the roadway are 9-in. 18-lb. I-beams, spaced about 2 ft. 4½ in. on centers, and calculated for a live load of 100 lb. per sq. ft. of roadway and for the concentrated load from a 15-ton motor truck. The sidewalk joists are 6-in. 15-lb. I-beams, calculated for a live load of 80 lb. per sq. ft. of sidewalk.

The live load capacities were assumed after a careful consideration of the data gathered by the late C. C. Schneider, Past-President, Am. Soc. C. E., and in the investigation of the Blackwell's Island Bridge in New York City.

The joists were fastened to the bridge stringers by 3 by 3 by ⅜-in. clips, bolted through the joist flange only. The 2½-in. hard pine sidewalk floor and the 3½-in. white oak roadway plank are fully spiked to pine spiking strips, which had been treated with hot carbolineum, and which are bolted to the top flanges of the steel joist. The curb was set back 4½ in. on each side of the road to give more roadway room, making the clear width 28 ft. 9 in. The plank was spiked with full ¼-in. openings to give proper drainage, and the spiking strip for carrying the ends of the sidewalk plank was spiked to a raising block 3 in. thick every 3 ft. to give plenty of opening for the dirt to be blown and scraped into the river. A protection of 3 by ¼-in. strap iron was spiked at the curb to the ends of the sidewalk plank, which had been previously treated against decay.

Highway Entrances.

The bridge when rebuilt in 1896 had a comparatively light highway traffic, and no need was found to give the greatest room possible for pedestrians and vehicles. The change made in the viaduct column bases to give about 4 ft. more roadway directly at the highway entrance has been described, and the fact noted that all the stone pedestals that were allowed to remain were cut to a batter to allow more hub room in the roadway, and they were curved out at the sidewalks to give more room for pedestrians. The width of the walks was further increased by cutting off the toll windows about 15 in., also the corner of the American toll-house to give about 20 in. more width. The

corner of the building was supported as an eccentric load on a special steel column and the space on each side turned into windows to give better light in the Customs Office.

The sidewalk to Whirlpool Street on the American side, about one and one-half blocks, was changed and landscaped with a curved walk to the north side of Mill Street, so as to avoid crossing the vehicle traffic twice. This change and a similar one across Mill Street made it possible very materially to add to the width of this street and to carry it practically full width to the bridge entrance. The railings to the small parks on both shores were improved, and reinforced concrete fence posts of a simple but neat design were used at the Canadian park. The same high standard as applied to the bridge itself was used in putting all the accessories in first-class condition to care for the present extensive highway traffic and to provide for future reasonable increase.

Sand-Blasting and Painting.

The paint on the structure was in very good condition, except as already detailed in regard to the upper work of the railway deck. It had been completely renewed three times in the preceding 22 years, with a 75% home-mixed white lead, zinc, and linseed oil paint. While no comprehensive method had been adopted in removing rust spots before applying the new coats of paint, the deterioration from rusting was practically nothing (except on the railway floor) on starting to clean the structure thoroughly with Mott sand-blast machines, and it was found that the original coats of red lead and white lead and zinc were intact over about 80% of the 480 000 sq. ft. of surface. Therefore, the sand-blasting was only used to clean off all dirt, loose and dead paint, and thoroughly to burrow out the small rust spots. As soon as possible after cleaning, these rust spots were coated with Tockolith to kill any small amount of rust missed, or the starting of incipient rust. The machines used for the sand-blasting were two No. 1 Mott sand-blasting machines and one No. 2.

When it was found that silica sand would cost more than $6 per ton delivered at the bridge from Illinois, several local sands were tried, and the dried locomotive sand procured from the Grand Trunk Railway roundhouse was found to be sharp enough to give the results desired. The maximum speed in cleaning reached as high as 25 to 30 sq. ft. of surface per min. and the entire cost of the work, including

labor, sand, and power, was close to 1 cent per sq. ft., so that the average reached was only about one-tenth of the maximum possible, due to lost time in charging sand, changing nozzles, building and changing scaffolds, and all the usual delays in work of this character. The interference from other classes of work under way was also a big factor in reducing the efficiency of the cleaning, and it would seem easily possible on an ordinary bridge with no other work in progress to reach an average of 6 to 8 sq. ft. per min. In any event, it proved to be the one best way properly and thoroughly to clean an old bridge. Improvements in the apparatus were made by reaming out a tapering entry for the sand in the inner ends of the loose nozzle tips, and by using bent nozzles for reaching surfaces that were difficult for the operator to get at, and for the inside of latticed members.

The carburetor on the machine should also be improved so as not to clog up with damp sand, as it was nearly impossible to keep the sand dry in only damp and foggy weather, while in wet weather work soon had to be practically suspended.

The great variety of conditions on various parts of the structure required the use of twelve different kinds of coatings, each one for a specific purpose, as will be briefly described. They were red lead, white lead and zinc, Tockolith, graphite, Galvanum, cement paint, fireproof paint, turpentine asphaltum, Hermastic enamel, enamel primer, carbolineum, and cement gun coating.

The red lead was 60% ready mixed, with asbestine and other suspension pigments. This was used for the shop assembling and first coat, but for the field 3 lb. of lamp black per bbl. was added to insure further the keeping of the red lead in suspension, to increase the spreading, and to darken it so the silver-gray lead paint would cover more easily. It was intended to use this for all metal fully exposed by the sand-blast as a first or spotting coat, but a study of conditions caused a change to Tockolith, as stated.

The white lead silver-gray color paint was for the finish coat. It was 60% white lead, 20% zinc, and 20% barytes and other pigments. The white lead and the zinc were each increased from 5 to 10% in the field, so as thoroughly to cover the darker paints.

The Tockolith was substituted for the red lead to cover rust spots after cleaning, as the writer's experience for several years in painting badly rusted metals has shown that this paint absorbs the oxygen from

rust and stops further rusting. The cutting apart of girders for reinforcing disclosed that where the surfaces had been painted with red lead between cover-plates and angles before shop assembling, all the paint had been practically burned out during riveting. Therefore, Tockolith was used for much of the assembling paint in the field.

The use of Superior graphite was deemed necessary on the bottom of the copper-steel floor to resist drippings from salt water, acids, and gases. One coat was used for this purpose and the second coat was the white lead finish paint. Graphite is undoubtedly one of the few paints that should be used for assembling, so as not to be burnt out in rivet driving. Possibly better results would be had by substituting something, at least in part, for the linseed oil.

The Galvanum was used for painting a few hundred square feet of galvanized corrugated-steel roofing between the girders at the Toll Offices. Ordinary paint could have been used by first washing the galvanizing with a weak muriatic acid solution, or by adding cut shellac to ordinary paint.

The cast-steel bases and boxed-in bases of the viaduct columns were filled with water-proofed concrete, formed with the addition of Medusa compound. To exclude the water further and to match up with the silver-gray coat on the bridge, Acme cement paint was used for painting the exposed surfaces of this concrete.

The use of Acme fireproof paint for the timber floor was investigated by painting some boxes and attempting to burn them. The results were so satisfactory that it has been recommended that the cracks in the roadway and sidewalk floors be sprayed with this paint as soon as the lumber dries out in the spring, in order to prevent fires starting from cigarette and cigar butts.

The elbows and inclined sections of the 4-in. steel-pipe downspouts were painted with turpentine asphaltum as a partial protection from salt water, since it was not possible under the conditions existing to use Hermastic enamel in this location.

The Hermastic enamel was used for coating the copper-steel drainage floor as a protection against the rusting or corrosion of the steel of the railway floor system due to salt water and other drippings. The copper-steel plates were also coated with this where they had a bearing on the maple risers, and in addition the maple was given a coat. The metal was first cleaned, then coated with the enamel primer, and the

Hermastic enamel applied with special daubers, while the enamel was very hot. Even then it would only spread a distance of 12 to 18 in. Owing principally to the thickness of the plates and the constant breeze or wind down the Gorge, about 50% excess of the enamel was used and the average thickness was more than ⅛ in.

Carbolineum was used for all timber treating, and it was generally applied hot with a brush, but the blocks were dipped in the kettles where it was heated. From one-fourth to one-half of coal oil was added to increase the spreading and penetration of the carbolineum. The timbers treated were the spiking strips for the highway floor, the maple risers and blocks for the tie-risers, as well as the stop-waters and other minor timber details.

The coating with cement mortar by the cement gun has been spoken of under the discussion of the skewbacks and only mention of it need be made here. The concrete abutments and walls were simply painted with a cement mortar cream.

Steel Repair Plant.

The steel construction plant used by the Terry and Tench Company, which did the construction work, was exceptionally complete. The three compressors of about 230 cu. ft. per min. capacity of free air, were of the motor-driven type such as has been used on elevated railway work in New York City. The motors are 50 h. p., 250 volts, and the whole equipment for both motor and compressor is mounted on steel wagon trucks. The electric current was obtained from the feed lines of the electric railways on either shore, and so no shut-down of the work was necessary when power was off at one end. They all fed into the same 2½-in. pipe extending the length of the bridge, and connecting to two air tank reservoirs. Frequent branches and valves were provided for connecting the hose for air drills, riveters, sand-blast machines, and cement gun. The long gun riveters were of the usual type, and the air drills and reamers were of the high-speed type running at 700 rev. per min., with drills and reamers to correspond, so that no difficulty was found in keeping work abreast. There were twelve riveters in use, and fifteen air drills and reamers.

The sand-blast machines were made by the Mott Sand Blast Company, of Brooklyn, N. Y., and as stated were three in number; the No. 1 size consuming 94 ft. of free air per min., and holding 500 lb. of sand;

while the No. 2 size consumed 94 ft. of free air per min. and held 1 000 lb. of sand. They consisted of a sand tank filled through a sieve at the top, and discharging through a conical bottom to the carburetor where the compressed air is introduced, all regulated by suitable valves. The discharge hose is of special heavy reinforced rubber, and carries a nozzle which has small hardened cast replaceable tips. These tips were those reamed out conically to allow freer discharge, and special bent nozzles were made to facilitate work which was often somewhat out of reach and partly inaccessible for the ordinary nozzle.

The oxy-acetylene torches for cutting were of the ordinary type, the burners or tips having three holes one above the other. They were used for cutting off old column bases, curving out gussets, cutting up old flange plates, and many other cuts which if made by hand would have taken hours instead of minutes. For cutting off rivet heads, the tips used for ordinary burning were slow and a special tip was used with three holes in line, which cut off an average of about 80 heads per hour and did not weld the shank of the rivets into the holes. No more valuable tool can be found for field repair work, and it can be used for any work where the danger of overheating the steel does not need to be considered.

The material was unloaded by a small "jiniwink" or shear-leg type of boom derrick, operated by an engine using compressed air, and was distributed over the highway deck as far as possible by means of a hook buggy and by several large lumber-yard buggies. Owing to the great height of the work above the Rapids and the necessity for keeping up traffic, double hitches and double slings were used, so that with constant watchfulness not one accident from this source occurred.

Rock Cliffs.

The cliffs at each end of the bridge were found to be quite solid when the arch was built to replace the Suspension Bridge in 1896, and therefore they were left with an overhang above a vertical cliff wall of 50 or 60 ft. in height. Some rock falls had occurred during the years following, one of which did some damage to the end shoe strut, really a tie, on the Canadian end of the arch. There had been some bad falls up and down the Gorge from the bridge, and as the cliffs were badly weathered, it was decided to remove all the loose rock and overhang which might, in falling, damage the arch span. This removal con-

sisted in taking off a 12-ft. overhang under the Canadian 115-ft. span, and an overhanging point directly adjacent to and north of this. The 8-ft. overhang under the 115-ft. span on the American end was also removed. The yardage was not a large total, but the rock had to be broken up into less than one-man stone before casting it over at the Canadian end, and before hoisting at the American end, on account of the electric railway down in the Gorge. The skewbacks and tracks were well protected by plank aprons. The rock was drilled in rows of holes for one cut, using hand air (or plug) drills, and the face finally left was practically smooth and vertical, but all the great superimposed weight was taken off and no future falls are expected.

Should future conditions warrant further protection, it is proposed to construct just above the skewbacks on either side a rock-catching abutment which will catch and retain a large quantity of small rock before a cleaning out would be necessary, and in the case of a large fall, would break its force and prevent its bouncing on to the steelwork. Such a device might be found useful in many similar locations where protection from rock falls is necessary.

Masonry Repairs.

The repair of existing masonry is usually more troublesome than building new; especially is it difficult to decide on a sure cure for trouble. This is usually due to the impossibility of knowing the condition of the interior of walls or masonry masses, except as its solidity may be learned from borings, and this method of testing is often far from satisfactory. Added to this difficulty, there was at Niagara the old suspension bridge abutments and anchorages in use for the abutments of the railway viaducts. These were built of limestone in 1855, making them 64 years old, and there were no plans in the files from which to determine their thickness and the character of construction.

Fortunately, the writer found at Van Nostrand's one of the original Roebling monographs on the Suspension Bridge, published in England, and in this were plates giving the masonry details. The front walls of the abutments which carried the girder spans were found to be about 9 ft. thick at the ground line; and this was later checked up when weep-holes were bored through them with a Burley drill carrying a 5-in. drill bit, in which to insert 4-in. steel drain pipes that

were also to extend through the new concrete face wall, which is described later.

The old suspension bridge towers, as has already been mentioned, were replaced with steel by Mr. L. L. Buck, and when the stonework was torn out from between the new steel members of the towers, the rock was found to be completely shattered or broken up in the interior. The abutment wall under the girders at the Canadian end was quite shattered from frost and traffic combined, so that it worked under passing trains and was considered to be unsafe. A heavy timber bent was erected to carry the traffic, and the face of the wall barred out to a depth of more than 1 ft., or to where it was quite compact under pressure. Forms were then built of 2-in. surfaced lumber and a new concrete face wall or carrying abutment was constructed. The girders were carried on this abutment using new cast-steel shoes, with new stiffeners riveted on the girders above the new support and on the webs between this and the first old pair, to care properly for the shear. The old end of the girder had the bearing-plates removed and now carries the track as a cantilever for the distance from the new bearing to the old back-wall.

The stone pedestals removed from beneath the viaduct columns on account of being cracked were found to be badly shattered, much the same as noted for the old towers and the old abutments. This led to devising a thorough method of protection of the skewback masonry of the arch from weathering, as it had only begun to show the effects of 22 years of exposure to the rigorous climate. The original scheme adopted had been simply to coat the limestone courses below the granite copings with a cement-gun finish, but on the developments in regard to the other masonry, it was decided to armor all four of the skewbacks as shown in Fig. 23, which also shows the thrust wall between them, which is described later.

The armor was shot on with a cement gun, the proportions of the coating being one of cement to one and one-half of clean sharp sand, with an air pressure of 40 lb. This coating was about 6 in. thick at the top, and more than 12 in. at the bottom of each skewback, as was necessary to get a regular batter line. The coating was reinforced by a triangular wire mesh which had first been fastened closely over the old stonework by spikes driven into the cement joints. This mesh had No. 9 longitudinal wires 4 in. apart and No. 12½ cross-wires 8 in. apart.

Just below the old coping a new coping was shot on, reinforced by a bowed-out strip of wire netting. The old coping therefore appears as a pedestal block.

The stone skewbacks were quite high and slender, especially on the American side, and under the most severe assumptions as to stresses from wind on the unloaded bridge, which is exceptionally high and exposed, it was found desirable to carry the directly applied stresses from the new sway bracing down to the solid rock foundation strata. The drilling of any holes through the skewback masonry for efficient tie-rods seemed undesirable, and, therefore, the skewbacks were connected by the thrust-walls shown in Fig. 23. These walls were 4 ft. thick, with a plain coping, and arched at the bottom to allow falling rocks and débris to pass through or be cleaned out, so that they would not eventually become retaining walls. Footings were built next to the skewbacks to carry each end of a wall. The reinforcing consisted of sixteen 1-in. deformed bars in diagonal lines from the top of one skewback to the bottom of the other, each bar being placed 6 in. into the masonry at each end in holes drilled with the plug drills. These holes were put into the tops of the high American skewbacks, slanting downward, so as to afford some tension anchorage. Each set of sixteen rods was hooped into a column as shown. The arched bottom was reinforced to act in conjunction with the shear rods, simply to prevent cracks in the wall.

The thrust-walls and the armor coating not only serve perfectly the structural purposes for which they were intended, but as may be seen from Fig. 28, they add much to the appearance of the structure, especially as to solidity and stability. They are also designed to serve as part of the enlarged skewbacks that will eventually be needed to carry additional ribs for a four-track bridge.

Deductions.

The data given as to increase of locomotive and train loads, supplemented by such other like data as have been published and which can easily be obtained, should be made the basis for negotiations by the Society with the leading railway societies and with locomotive and car builders as to the allowable increases for a reasonable time in the future. This would make it possible to plan more definitely than could otherwise be done for the strength of future bridge construction. The great

requirements for steel in all classes of work in which iron and steel are utilized makes it certain that from every viewpoint raw supplies for the manufacture of iron and steel structures must be conserved.

The information presented as to the great diversity of possible bridge loadings now in use, and the distribution of stresses occurring in structures as compared to calculated stresses, indicates the great futility of over-refinement. Although the system of composite loading proposed may prove to be no more than tentative, it is certainly to be hoped that it will be made the basis by the Society, and others interested for the adoption of a comprehensive, logical, and simple system. This can certainly be done, and be a credit to that branch of engineering which lays claim to being the most scientific of the many specialties now comprised under the general head of Civil Engineering.

The strain-gauge results obtained, while not perfect, certainly indicate the necessity of making both dead load and live load readings of representative members of all important structures. The gauge points should be permanent, put on the members and read before erection, to the end that the bridge engineer may at any time easily make a check of actual stresses and their distribution, as caused by standard trains. Should such a scheme be instituted by the large railway systems, it would then be possible, with the aid of the United States Bureau of Standards, to obtain extensive and conclusive data as to impact on bridges, as to secondary stresses, as to distribution of stress over the cross-section of members, and, finally, to obtain much valuable data as to the strength of compression members and members undergoing reversal of stress. The needed information to supplement this kind of data on compression members could also be easily obtained if each railway would substitute for full-sized eye-bar tests, the testing of one or two compression members for each important structure. This would probably corroborate recent data from tests that indicate the need of better compression member details, rather than any change in the sections themselves or in their make-up.

The stress readjustment carried out in the Niagara Arch, by using toggles to change the center shim, is seldom possible of attainment in the ordinary structure, but it is not too much to say that there is a logical way possible for the revision of most large structures, and the strain gauge would play no small part in accomplishing the desired result. The great lesson to be learned from this Niagara revision and

the examples of the first Quebec and the Blackwell's Island Bridges, together with the success obtained for the Hell Gate Arch, is that the real design of a structure does not lie entirely in computing stresses and designing details, but in the greater problem of the most fitting general design for a given location and as a general scientific problem. The writer does not hesitate to repeat a statement often made heretofore, that engineers cannot properly design a bridge unless they have made every effort to give it the proper æsthetic consideration, with the assurance that in so doing they need not violate the principles of scientific design, nor of the truest economy.

The investigation at Niagara emphasizes the need for the engineer of any important structure to leave the most complete data possible in the files of the owners. This should not merely include blue prints and specifications, but copies of all computations, stress sheets, and data as to the construction, and of practical details of the work. Such information is not only of value as relating to the particular bridge, but will result in more exact scientific data being obtained whenever such a bridge is under investigation.

The scientific investigation of the Niagara Arch was made financially possible through the courtesy of George L. Burrows, Assoc. Am. Soc. C. E., President of the Niagara Falls International Bridge Company, and Charles Riordon, President of the Niagara Falls Suspension Bridge Company, joint owners of the bridge. The field and office work was carried out with the assistance, during 1918 and 1919, of C. T. Morris and A. H. Fuller, Members, Am. Soc. C. E. The Resident Engineer on construction was H. A. Reid, Assoc. M. Am. Soc. C. E.; and acknowledgment is also made for the assistance rendered by F. L. C. Bond, Chief Engineer, and H. B. Stuart, Structural Engineer, of the Grand Trunk Railway, and by P. L. Wolfel, M. Am. Soc. C. E.; also to H. G. Dickinson, Superintendent for the Bridge Companies; and to The Terry and Tench Company and the Lackawanna Bridge Company, contractors for construction and fabrication, respectively.

DISCUSSION

Mr. Ammann.

O. H. AMMANN,* M. AM. SOC. C. E.—The author deserves much credit for the careful and thorough manner in which the revision of the Niagara Bridge has been carried out, as well as for the elaborate experimental investigation conducted in connection therewith. The redesigning and reinforcing of the bridge is in accordance with the most advanced practice and should give the structure an additional useful life equal to that of a new one.

Experimental investigations such as those made on this bridge are most valuable in giving engineers knowledge of the exact stress conditions, and for this purpose cannot be too strongly encouraged nor too painstakingly carried out. The knowledge gained, however, must be applied in a broad sense and above all with a view to the improvement of the excellence of the design rather than to economy by excessive refinement.

Bridge building is still an art, and as such its success depends largely on broad vision and judgment in the combination of the many intricate and changeable elements which enter into the design and which cannot, by themselves, and still less in their combined action, be determined exactly by scientific laws. A liberal margin in the selection of these elements therefore is justified. From this point of view, the speaker takes exception to some of the suggestions for revision in bridge design made by the author.

The author proposes the abandonment of Cooper's engine loading and the substitution therefor of the composite moment and shear curves or tables derived from some of the recent heaviest locomotives.

Although Cooper's loading is not an ideal one for all cases, it covers, probably more than any other loading proposed, the widest variety of engine and train loads. It has become a standard with which other loadings, past and present, are comparable in weight and axle loads, as well as moments and shears produced. Compromise moment and shear curves do not allow as simple and tangible comparison, because they do not represent any particular loading; and what guarantee is there that such curves may not, within a short time, become even less representative of actual loads than Cooper's loading? They at least are not representative of the large number of engine loads which are still prevalent on many roads and which must be taken into consideration in establishing a general representative loading.

Even if only the four extreme actual loadings selected by the author are taken as a basis, the speaker would consider Cooper's E-66 fairly representative, because the greatest excess of moments and shears from these extreme loads over those from E-66 would not be more than 15% and this only in very short spans. This is not excessive, con-

* South Amboy, N. J.

sidering that the moments and shears from the four locomotives differ as much as 40% among themselves. Mr. Ammann.

The author's composite moments are in excess of those from the actual loads by amounts up to 30%, not considering the additional 25% allowed for future increase of the loads; and inasmuch as this excess would affect the great number of small spans, it would not seem to be conducive to good economy.

For spans greater than about 250 ft., Cooper's loading appears to give excessive results. It must be considered, however, that the excess is not due so much to the engine loads as it is to the train load behind the engines. This load is more apt to increase in the future than the average weight per foot of the engine. Moreover, in longer spans, an excess in the live load produces a proportionately much smaller excess in the total stresses or sections than in smaller spans.

The speaker, therefore, believes that there is not sufficient ground for the abandonment of Cooper's loading, but that, on the contrary, it will become, even to a wider extent than in the past, the standard loading for designing railroad bridges.

The author introduces a new impact formula based on the train speed. Although in isolated cases it may be justified to design a bridge for limited speed, as was done in the case of the Niagara Arch, it is questionable whether a formula can be established which would be generally applicable, because impact is dependent on many factors other than speed.

In the Niagara Bridge the impact for various speeds was determined from careful readings, and there can be no doubt that the curve thus established is correct and justified a reduction in the impact allowance in redesigning the bridge. For other bridges the curve may be entirely different, mainly because the critical speed causing maximum impact is dependent on the type of bridge, span length, dead weight, and even on the live load itself. Only extensive series of tests would shed further light on this question, and for lack of additional data it is safer to design bridges with full impact allowance.

The author's adoption of high permissible unit stresses of about two-thirds of the elastic limit and his application of them to the combined stresses from all sources, is a step in the right direction. In the speaker's opinion, it would not have been necessary, however, to include the secondary stresses in the maximum stresses, because they are nowhere excessive except in a few members, which, for constructive reasons, have an excess section.

In general, secondary stresses may be assumed to be safely covered by the one-third margin of safety below the elastic limit, provided care has been taken in the design to avoid large secondary stresses. It is safe to say that, by reason of greater rigidity and superior details,

Mr. Ammann. bridges designed according to good modern practice and in which excessive secondary stresses are avoided, have a greater margin of safety than former bridges in which the secondary stresses were not even investigated.

The author's compression formula is well chosen in view of the experimental data gained during the past few years and, as a simple straight line formula, deserves general adaption in cases where high unit stresses are chosen.

Recent attempts to introduce apparently more refined formulas are not warranted. What engineers need more than an ideal formula is improved practice in designing compression members, so that they will develop the full strength attributed to them.

Mr. Bentham. C. BENTHAM,* ESQ.—The author states that the bridge was constructed of what is termed in the United States as medium steel, and that the rivets are of soft steel; he also mentioned that some of the rivets came loose. This may be due to a number of causes. In bridge construction in England, especially over tidal waters, trouble has been experienced with the rivets in steel bridges, and it has been thought that electrolytic action between the rivets and plates when of different material is intensified by the salt water. In the Forth Bridge, numerous rivets have been replaced because corrosion has occurred between the plate and the head of the rivet. Corrosion of the plates appears to be more intense with those of modern steel than with those of wrought iron. The bottom parts of the tubular supports of the Forth Bridge are rusting away because of waves beating over them.

In answer to the question as to whether the renewal of the girders was on both the railroad decking and the road decking, the author states that only the girders on the railway deck were renewed as the salt water from the refrigerator cars did not get down to the lower deck. One of the photographs shows the bridge with all the track removed and all the girders exposed, and yet the author states that the work continued without interference with traffic, explaining that in a double-track bridge, one track was kept clear while the other was being renewed. The floor-beams, he states, extended across the width of the bridge, and the engineers shored up and took the cover-plates off the floor-beams without interference with traffic.

This point is not quite clear to the speaker because it looks, from the photograph, as if the whole deck had been taken off. In regard to this loading weight, it has been found that many of the earlier English bridges are far too weak, according to the present-day formulas. A number of them have been stiffened, but there is one bridge in particular, constructed by Brunel at Chepstow, about 1840, where it was found that the stress was above the elastic limit of the wrought iron

* Manchester, England.

used in the construction. That bridge stood for forty years. It has been stiffened, because the weights have been increased; with the loads as calculated, however, it should have broken down many times in those years, but it did not do so. As the weight of the locomotives increased, the speed was reduced to a limit of 10 miles per hour over the bridge. Presumably, this is partly what was done at Niagara before the bridge was stiffened, the speed of the trains being gradually decreased as the train loads were increased. Mr. Bentham.

The critical speed of the average train in relation to any particular bridge is an important factor, because, when ascertained, the members of the bridge may be safely stressed more nearly to their elastic limit if this particular speed can be avoided.

The author has mentioned the greater utilization of the water power of the Rapids, and he is probably aware of what is now being done. The Ontario Hydro-Electric Commissioners are at the present time carrying out a scheme which utilizes the entire head of the water with the exception of that which is necessary for hydraulic flow. The water is being used up to a head of about 300 ft., whereas at the existing power stations the head is about 160 ft. The benefit of the Rapids below the Falls in addition to the Rapids above the Falls, is being obtained.

J. A. L. WADDELL,* M. AM. SOC. C. E. (by letter).—This paper is one of the most interesting and instructive treatises on bridgework that has appeared in a long time. The labor involved in its preparation must have been very great, and the author deserves the hearty thanks of the Engineering Profession in general, and of bridge specialists in particular, for his able efforts on behalf of his brother engineers. The historical features of the paper are specially interesting and valuable, because far too little is either recorded or generally known concerning the history of engineering. Again, the dissertation on live load augmentation is most instructive. The writer agrees with Mr. Fowler that the time for abandoning the Cooper type of loading has arrived, but thinks that curves of equivalent uniform live loads should be given in specifications for design, rather than the irregular concentrated loads. These curves should not follow exactly the equivalents for any particular locomotives, but should envelop on the diagram most of the plotted points for the equivalent uniform loads of a number of modern or possible future engines. In predictions concerning future live loads, it must not be forgotten that for the roadbed the present style of track is loaded about all it will stand, so that any seriously greater burden will have to be distributed in some more uniform manner than is attainable by the arrangement of rails and ties used generally in America. Mr. Waddell.

* New York City.

Mr. Waddell.

In pointing out "the need of better compression member details, rather than any change in the sections themselves or in their make-up", Mr. Fowler has struck the keynote in reference to the proportioning of struts, concerning which there has been so much discussion of late; and it is evident that, like the writer, he does not see any real *raison d'être* for the panic about the alleged weakness of the old standard compression formulas initiated by the Society's Special Committee on Steel Columns and Struts in its final report.*

The writer is in accord with the author also when the latter says that "the real design of a structure does not lie entirely in computing stresses and designing details, but in the greater problem of the most fitting general design for a given location", and also when he states that a proper consideration of æsthetics will not violate the principles of scientific design nor those of the truest economy.

Bridge designers in general, and especially young men who are studying the specialty, will do well to hearken to these words of wisdom from one who, by years of experience in designing and construction, deep study of theory and principles, and the writing of standard works, has established himself as one of the highest authorities in bridgework.

Mr. Belzner.

THEODORE BELZNER,† ASSOC. AM. SOC. C. E. (by letter).—The author is to be congratulated in presenting to the Engineering Profession, and to the members of this Society in particular, such an interesting and important paper.

In reference to the comparative readings to determine the respective accuracy of the Berry, Howard, and Fuller-West strain gauges, it would be of interest to the writer to know the relative accuracy of the Howard gauge for static load readings, as compared with the other two instruments.

During the strengthening of the end spans of the Williamsburg Bridge some years ago, the Department of Bridges of the City of New York, in co-operation with the United States Bureau of Standards, under the auspices of James E. Howard, Engineer Physicist, conducted a comprehensive series of extensometer investigations on the important truss members at the main towers of that bridge and on the legs of the Brooklyn intermediate towers.

The writer had the good fortune of being assigned to these investigations by the late Austin Lord Bowman, M. Am. Soc. C. E., then Chief Engineer of the Department of Bridges. He also had the pleasure of being associated with Mr. Howard from the beginning to the completion of this work, and became thoroughly grounded in the importance of precision in such work in order to secure the best results.

* See p. 1583.

† Brooklyn, N. Y.

Mr. Belzner.

A 20-in. Howard extensometer was used throughout the entire investigation, and the precision attainable with the strain gauge and its reliability in measuring stresses proved it to be an invaluable aid to the Bureau of Design of the Bridge Department in arriving at the conclusions on which the successful issue of the work was based. Its merits were illustrated in certain vital operations, especially in connection with the various stages of the wedging operation, and in the transferring of stresses from the old to the new diagonal members of the end trusses. The accuracy of these results has been discussed by Isidore Delson,* Assoc. M. Am. C. E., Assistant Engineer, Department of Bridges.

D. B. Steinman, M. Am. Soc. C. E., in his exceedingly valuable paper entitled, "Stress Measurements on the Hell Gate Arch Bridge",† has described the Howard strain gauge so fully, the methods of its operation, and the precaution required in its use for precise work, that little can be added, except, possibly, a few references to methods of making the measurements. After the preliminary work on the members to be measured, the most important point to be considered is in obtaining consistent measurements, and this point cannot be emphasized too strongly. In order to secure such results, which are absolutely essential, persistent patience and painstaking thoroughness, combined with good judgment on the part of the observer, are required until he gains perfect control of the instrument, after which he will experience little or no difficulty; and it is upon the observer that the value of such measurements will depend.

Another fact to be remembered is that all measurements should be taken during the early morning hours, preferably before sunrise in summer, and on cloudy days, in order to eliminate any possible internal temperature strains in the members.

The writer's experience with the operation of the Howard extensometer, extending over a long period of measurements, has been that the use of the inside milled head is preferable, on account of the sensitiveness of touch for contact, and he agrees with Dr. Steinman‡ that it "is probably the simplest and most accurate field instrument for measuring strains."

It may be of interest to state that, in September, 1913, during the stress investigations on the Williamsburg Bridge, Mr. Howard tried out, on the stiffening trusses, a new strain gauge which he had designed for measuring live load stresses. This instrument is about 3 in. long and 1¼ in. wide, and might be properly termed a "scissors-gauge". This gauge has been fully described in an article entitled "A New Strain Gauge for Live Load Stresses".§

Mr. Schmitt.

F. E. SCHMITT,* M. AM. SOC. C. E. (by letter).—As the first instance of large-scale bridge reinforcement on the basis of thorough analysis by measurement of stresses, the work described by Mr. Fowler is not only notable in itself, but also presents a valuable model for future work in this field. The revision was greatly simplified by the excess of strength originally provided in the arch rib, which made it unnecessary to add material to the arch members. Nevertheless, the impressive fact is made known by the author's account that the operations described extend the life of the Niagara Railway Arch indefinitely, without impairment of efficiency in the utilization of its material. This is a new achievement, and one of great importance. It is particularly noteworthy because it is based on investigations which are truly scientific, including separate studies of condition and behavior of structure, nature of service, and capacity of material. Since these studies were essential to the results, it is fair to assume that similar investigations, at least for service stresses, will be found necessary in future cases of reinforcement of steel structures, if the results are to measure up to the possibilities.

The reinforcement of large bridges has been undertaken but rarely. In large part this must be charged to the fact that bridge practice progressed continuously, and that when a bridge was outgrown by the traffic loads it was almost necessarily replaced by a new one of better type. In the railway bridge field, conditions have changed sufficiently to eliminate this necessity, so far as structures of recent date are concerned. As bridges are built to-day, they may be considered virtually proof against "wearing out" or obsolescence of like character. Change in amount and kind of loading is the chief future contingency, and this may be dealt with by reinforcement. Therefore, less bridge replacement and more reinforcement work would appear to be in order for the future.

Bearing directly on this question is the remarkable demonstration of the longevity of well-built and well-maintained steel bridges afforded by the Niagara Arch. After having done service for more than twenty years, the bridge proves to have been essentially free from deterioration in its primary parts. Steel bridges have been regarded as inherently short-lived, but the Niagara example makes this view untenable. It shows that steel bridges may be made permanent structures, the original investment in which is a fixed asset. To realize permanence it is necessary, however, that the designer exercise sufficient foresight to guard against destruction of service value by obsolescence, that maintenance be attended to, and that a high degree of thought and skill be applied to reinforcement (when this is called for), perhaps

* New York City.

even greater skill than is ordinarily applied to bridge construction and replacement. Mr. Schmitt.

In connection with the first of these requirements, it is pertinent to remark that, since designing for indefinite future increase of loading is usually impossible, attention at the time of original design to the likelihood of future reinforcement should be worth while. It is safe to say that few if any bridges have been planned with this point in mind, but there is no reason why the design should not be worked out so as to simplify reinforcement at a later period. An incidental advantage would be gained, which is by no means negligible: When the planning of a bridge is guided by the purpose of producing a permanent structure and providing in advance for future operations to adapt it to changed service, a design of far higher character will result than when the controlling thought is that the structure will have only a moderate life, on account of deterioration or change of service requirements.

To make reinforcement ideally efficient, both old and new materials must be utilized to full capacity. Something has been done in developing methods to secure this object. The remarkably well conceived crown-shim readjustment to distribute the dead load stresses of the arch more favorably, and the toggle device used in reinforcing the posts of the Niagara truss spans, as well as the successful use at Poughkeepsie of heating in attaching reinforcing plates, fall in this category, and deserve high appreciation on the score of simplicity and effectiveness. However, there can hardly be a doubt that methods to accomplish equal division of service between old and new material will be developed much more extensively in the future than in the past. In work so variable and so dependent on the engineer's resourcefulness as bridge reinforcement, it seems to be inevitable that a much broader range of available methods must be worked out to meet the many complex sets of conditions arising in practice. It may be expected therefore that with the expansion of reinforcement work the development of the structural art will enter on a new phase.

As the first step in reinforcement work, or even in the preliminaries leading up to a decision on the question of replacement or reinforcement, is the determination of actual effects of service, the relation between calculation and measurement of stresses calls for consideration. In the writer's opinion there is usually enough uncertainty about the distribution of stress in a structure, particularly in one that has been long in service, to make strain-gauge measurements indispensable to a satisfactorily thorough knowledge of service effects. Relatively few comparisons of calculated and measured stresses have been made, from

Mr. Schmitt: which a good judgment of the relation between them could be formed; but these indicate that even with respect to primary stresses the check is only approximate, especially under moving loads, while stress variations over the cross-sections of members, and numerous other auxiliary effects, create very serious divergences between measurement and calculation. In considering questions of reinforcement, the measured stresses will naturally be accorded determinative weight, and calculation will be regarded only as a check. It is thus possible by means of measurement to adapt the distribution of material in a structure much more closely to the actual stresses developed in service than is possible in constructing a new bridge, a point worth special consideration as suggesting that a distinctly higher efficiency can be reached in reconstructing an existing bridge than in building a new one.

With regard to the use of strain gauges for the measurement of live load stresses, the fact is not very prominently dwelt on by the author that even in a constrained structure, such as the Niagara Arch, these stresses are as definitely calculable as in simple structures, except for two factors: The influence of details and possible looseness at a support. The latter can be determined and evaluated by inspection; the influence of details, on the other hand, is likely to be difficult to estimate, because of the lack of suitable data. Deflection observations on bridges of either simple or constrained type would supply such data, but observations of this kind are rare.

Apart from the question of influence of details, the primary live load stresses in the Niagara Arch should have been determinable as accurately by computation as in any type of bridge. The results of the measurements and comparisons make it clear, however, that secondary and impact effects are of such magnitude as to give them an importance from the designer's viewpoint equal to that of the primary stresses; and very obviously, according to the results, these secondary and impact effects must be measured by the strain gauge rather than be approximated by rule-of-thumb formulas which were framed to provide allowances suitable in new design.

Dead load stresses appear not to have been a matter of much concern in the Niagara case. It is to be considered, however, that where such service is placed on metal as in the revised Niagara Arch, in other words, where a high efficiency of utilization of material is aimed at, the dead load stresses should be known quite accurately. The crown jacking which was done to give a datum point for the calculation of dead load stresses supplied no further information than that it removed the statical uncertainty due to constraint. It did not give fuller knowledge of actual dead load stresses than is available in the case of a simple structure without any measurement whatever. It is of some interest to speculate on what methods might have been used, and at

what cost, to make direct measurements of the dead load stresses existing in one or two important members. The writer, however, believes the case is most valuable in again directing attention to the proposal made some years ago by Mr. James E. Howard, that gauge points for measuring stress deformations be provided on the members of important structures before erection. When such points are placed, in permanent fashion, and initial measurements are made, stresses can be measured in a reliable manner at any time during the life of the structure. The measurements made by Mr. Howard on the Armour-Swift-Burlington Bridge, at Kansas City, and on one or two other bridges, besides several buildings, constitute a thoroughly practical demonstration of what may be done in this direction. The importance of his suggestion and its practical demonstration do not seem to have been fully appreciated. Renewed reference to Mr. Howard's work is believed to be justified by the fact that, in so important an undertaking as the Niagara revision, a distinct uncertainty surrounds the dead load stresses which constitute a very respectable proportion of the total stresses and hence of the utilized strength of the members. Mr. Schmitt

With regard to the whole subject of the permanence of bridges, the facts brought out in the paper as to the condition of the floor-beam flanges and the stringers are highly significant. The figures given as to deterioration of the floor are in alarming contrast to the statements as to the excellent condition of the primary members of the bridge. Although it is true that floor material usually can be renewed without great difficulty, yet the rapid loss of strength due to corrosion would make it seem a desirable safeguard and economy to attempt to provide better protection for floors than is given by the ordinary undrained, open-tie, floor construction which is virtually standard in railway bridge practice. The Niagara drip-plate protection is an ingenious and praiseworthy solution of the problem encountered there, but its value for general use is likely to depend on the maintenance which it requires. Experience with these drainage plates will need to be awaited as to this point. Although the last report of field tests of the Committee on Corrosion of the American Society for Testing Materials, made public after the presentation of the author's paper, indicates that copper-bearing steel is distinctly more resistant to corrosion than non-copper-bearing steel, yet the differences are not large enough to make the plates give promise of anything beyond a very short life. However, in spite of the use of thin steel plates in a substantially horizontal position, and wooden packing blocks which are also likely to be subject to rapid deterioration, the arrangement adopted has the great advantage of protecting thoroughly all the carrying parts of the structure and concentrating the deterioration in easily renewable parts, where ordinary maintenance can take care of them and continue the protection of the structure unimpaired.

Mr. Schmitt.

Besides bringing to the front important matters concerning bridge reconstruction, however, the paper raises numerous open questions and doubtful points in bridge design. Among these are railway loadings, impact effects, permissible unit stresses, the importance of secondary stresses, the suppression of vibration, etc. The vital way in which these points were involved in the Niagara work seems likely to open up anew a discussion on various phases of bridge construction, which by many have been regarded as practically settled. It is hoped, therefore, that full discussion of the matters in question will develop, and that the experience and opinions of practical bridge engineers may be brought out in a representative way. Although the paper gives only a small range of data on some of the matters concerned and most of these data are of quite inconclusive character, the method of attack used was effective and satisfactory, and (since sound and serviceable results were obtained) the data given in so far as they bear on bridge design are entitled to careful consideration.

The wide departure of the procedure followed in the Niagara work from that prescribed in standard bridge specifications suggests that a committee of this Society on bridge specifications, as recently proposed, would find ample work to do. One point with which such a committee might have to concern itself is unfortunately passed over in the paper without discussion, namely, the treatment of reversed stresses. In consequence, it is not very easy to determine the relative margins of safety in the main chord members and the web of the structure. According to the prevailing design practice of to-day, members subject to stress reversal are proportioned with increased section and still further increased connections, but there appears to be no agreement as to whether this is done because stress reversal has an injurious effect on the metal or its connections, or whether it is a contingency allowance for change in loading (in view of the fact that increased loading has most unfavorable effect on these particular members). The writer knows of no data from test or service observations to support the view that stress reversal, such as occurs in bridges, has any effect on the metal aside from that measured by the maximum stress. If reversed stress clauses are really intended to provide for load increase, this purpose might be expressed more properly in the wording of the clause. In any event, reversed stresses are not likely to have the same meaning in reconstruction as in new design.

Two points bearing on design requirements will be commented on here, namely, reduction of vibration and the selection of a loading system for design.

So far as the paper gives information, it is not possible to judge whether the reported virtual elimination of sway and vibration by putting in rigid bracing between the arch posts was due to the increased section of bracing thereby provided, or to the fact that the new brac-

ing is of the rigid type. Conceding that prejudice against light rod bracing is well founded, one may fairly ask if any data exist to show whether rod bracing of more ample proportion, well detailed, and properly adjusted, may not make a structure fully as rigid as stiff bracing. On this matter of rigidity, existing specifications fail to give any useful advice. Some guidance seems desirable, however, for there is a wide interval between the extremely light sway rods of former days and the surprisingly massive bracing found in many modern bridges. The best practice may lie between these extremes. Further, considering rigid bracing, it is proper to take note of the lateral secondary stresses which it induces in the main members; the effect of these secondaries is beneficial in only a very minor degree, and, on the other hand, may be distinctly harmful, particularly in tension members. Mr. Schmitt.

Whether or not the adjustment of the sway rods by the strain-gauge check carried out in 1918 was of service in stiffening the bridge, is not explicitly stated by the author, but it may be inferred that some decrease of side sway was thought to have resulted. Was the author able to form any specific opinion on the degree of initial stressing and the ratio between the sway-rod section and the main section, which will tend to assure that the bracing will be taut and the structure rigid under all service conditions? Also, in dealing with the old rod sways between the long posts, did he observe anything that would tend to show whether ordinary loop ends are too yielding for efficient service of sway rods fitted with such ends?

Commenting on the author's recommendation of a composite load system, selected to correspond to the maximum of various modern traffic loads, O. H. Ammann, M. Am. Soc. C. E., dissented from the view that Cooper's system of loading should be discarded, and referred to the moment curve in Fig. 4, as demonstrating the satisfactory character of the Cooper loadings. This diagram shows clearly, however, that the old system has a marked deficiency when applied to moderate span lengths, and an even more marked excess when applied to long spans. Practical considerations would counsel an opposite relation. In any event, it is plain from the diagram that maximum present-day traffic is not represented by any one Cooper loading for all spans. To produce a bridge of uniform strength under modern traffic, it is necessary to design the floor for one Cooper loading, the chords for another, and the web members for one or more other loadings; and in the case of a multi-span bridge, different spans must be designed for different sets of Cooper loadings. Thus, the Cooper class name is no longer a designating index number of the capacity of a bridge; calling a bridge an E-55 structure does not mean that it is adequate to carry a certain class of modern traffic. This is a practical disadvantage the importance of which the bridge engineer is more apt to underrate than the bridge user.

Mr. Schmitt

A load system more in accord with present-day railway practice would avoid this disadvantage. It is not wholly clear, however, that the substitution of another system which also requires a group of loadings to represent a single weight of traffic, as proposed by the author, would be an improvement. It should be possible to discover a suitable single loading, whether of the wheel load or of the uniform-load type; such a system should have more regard for probable future development in load distribution than for present-day loading.

Before a load system is finally formulated, it might be proper to take note of what was shown by the earliest work* of the Special Committee on Stresses in Railroad Track, namely, that the weight of a group of concentrations on an ordinary roadbed is distributed to such an extent that the effect of the individual wheels virtually disappears. It may be that a similar distribution of load effect occurs when the track is supported by a bridge floor, and some of the author's statements indeed suggest this fact. In that event, the problem of representing train effect by a conventionalized loading system would be much simplified.

In regard to the behavior of bridges, it is necessary to take careful note of one surprising fact reported by the author: That after the readjustment of the dead load stress in the arch at the crown, the completion of the readjustment after the change of shims occurred very gradually. It would appear from this observation that even in a bridge of fully elastic type, inelastic elements have an unexpectedly large influence. Without knowing more about the circumstances than is reported in the paper, one can only judge that the floor stringers, and, perhaps, in some small degree, the rails, were responsible for the lag in adjustment. In any structure likely to be affected by similar inelastic lag, it would evidently be necessary to take particular precautions in conducting a deflection test, in order to obtain a true reading of elastic deflection.

Taken as a whole, the facts developed in Mr. Fowler's investigation, and throughout the subsequent revision of the structure, constitute a most gratifying testimonial to the excellence of the design embodied in the original bridge. It does not seem to be extravagant to say that the design was a generation ahead of its time.

Mr. Lang.

P. G. LANG, JR.,† ASSOC. M. AM. SOC. C. E. (by letter).—The author states that "the logical procedure for new bridges, however, seems to be to abandon the Cooper loading entirely."

The use of the Cooper loadings has been the subject of much discussion. The engines shown in Columns 1, 2, 3, and 4 of Table 1 cover moments for engines of the Mallet and Santa Fé types only. If a careful study is made of all the various types of engines in use on the railroads to-day, and these engines are compared with the

* *Transactions*, Am. Soc. C. E., Vol. LXXXII (1918), p. 1191.

† Baltimore, Md.

Cooper series of loadings, the fact will become apparent that the Cooper loadings reflect the composite of all types of engines for all span lengths more nearly than any other typical loading which may be used. This matter has been very fully discussed in a paper* written by Mr. W. S. Bouton and H. T. Welty, M. Am. Soc. C. E. Mr. Lang.

In regard to the new railway floor, the statement is made that plates and angles, originally from $\frac{3}{8}$ to $\frac{1}{2}$ in. thick, were wasted away on an average of 50%, and that, in extreme cases, only a thickness of from $\frac{1}{8}$ to $\frac{1}{16}$ in. remains.

The writer's wide experience in the inspection and observation of old bridges inclines him to the belief that this statement, in the form published, conveys an impression at variance with that intended by the author. It appears to be improbable that a plate $\frac{3}{8}$ in. thick would be reduced, by corrosion, to a thickness of $\frac{1}{16}$ in. The writer's observation of such cases has practically always indicated that plates and angles corrode when placed in a horizontal plane, and that the corrosion begins at the edge. In the case of the horizontal leg of an angle, for example, the edge may be corroded to a thickness of $\frac{1}{16}$ in., but, at the root, the original thickness is obtained.

In regard to the highway floor, data concerning the axle loads and wheel spacing of the 15-ton motor truck used in the design would be a matter of much interest. For a bridge of this character, on an international highway, a 15-ton motor truck is, it would seem, not an excessive live load to use in designing the floor.

In a bridge carrying both railroad and highway traffic, it appears somewhat inconsistent to design the roadway floor for a 15-ton motor truck and the railroad structure capable of carrying Cooper's E-80 loading. That is, in the design of the highway structure, the margin of increase over actual current requirements appears small when compared with the greater allowance made in the case of the railroad bridge. It may be, however, that the highway floor has an ultimate capacity considerably in excess of a 15-ton motor truck. In this connection, it would be interesting to know the maximum load which may be passed over the highway floor.

JAMES E. HOWARD,† ESQ. (by letter).—It is gratifying to have another example presented of the use of the strain gauge on so important a piece of work as the Niagara Railway Arch Bridge, conducted in so satisfactory a manner. It has seemed that the Engineering Profession at large has not adequately realized the practical advantages which the use of the strain gauge affords. In the hands of those skilled in the making of refined measurements, and applied generously to Mr. Howard.

* Appendix D, *Bulletin No. 223*, Am. Ry. Eng. Assoc.
† Washington, D. C.

Mr. Howard.

engineering works of magnitude, no errors of computation, fabrication, erection, or subsequent use could reasonably escape detection.

Reference marks established on permanent structures can be re-examined; exact information on the distribution of stresses in the primitive loading of the structures and on their subsequent endurance of dead loads can be obtained; the re-distribution of stresses after repeated live loads have been received can be ascertained; and modifications in built-up members resulting from exposure to thermal changes, if such occur, can be determined.

It is a refined method of examination. The strain gauge as an instrument is a simple one, its adaptability of wide degree. The manipulative skill requisite to obtain reliable results is not in the possession of all. Fully realizing the care which must be exercised in its use, the strain gauge which bears the name of the writer was devised with the view of minimizing personal and instrumental errors. It has so chanced, however, that certain details of design which were carefully avoided have been used in other gauges where they appear to be held in esteem, as constituting the meritorious features of the modifications.

It is believed to be desirable to use a rectilinear movement in an instrument of this kind, and this was provided in the present form of gauge designed for field use, but which is merely a modification of an extensometer designed by the writer and first used some thirty-five years ago. The prototype of the present instrument is still being used for strain-gauge purposes, and is adapted for any gauged length between 1 in. and 30 in. The usual range for a 20-in. strain gauge is $\frac{1}{2}$ in. with zero line at mid-stroke. The readings of a rectilinear instrument are reliable at all parts of its stroke, which is limited only by the capacity of the micrometer screw used, which if desired may have a range of 1 in. or more.

On measured strains in steel members, a limited range only in capacity of the gauge is essential. On other classes of strain-gauge work, $\frac{1}{2}$-in. capacity has not been found to be too great.

On horizontal surfaces the gauge is self-centering. On other surfaces it must be firmly held against the measured member and micrometer readings taken by a second party. The pressure applied in so doing should be directly over the contact points. If so applied, there will be no springing of the parts of the gauge. Overhanging handles were not considered in designing the instrument.

In respect to the choice of material, steel was used. Its advantages are a high modulus of elasticity and high elastic limit. Some authorities give high nickel alloys—35 to 38% nickel—an elastic limit above 60 000 lb. per sq. in. The writer's tests on a 30% nickel alloy showed

an elastic limit of less than 20 000 lb. per sq. in., with a modulus of elasticity about 7 000 000 lower than that of steel. Mr. Howard.

The strain gauge is a transfer instrument. Hence, its coefficient of expansion is a negligible matter provided changes in length do not occur with rapidity. No more than 5 sec. need elapse between readings on the measured member and on the standard bar, to which all readings are referred. Within this interval of time the change in length of the strain gauge is not a sensible amount.

A standard bar of annealed steel, with planed surfaces, is used. Forged and rolled shapes commonly retain internal strains of considerable magnitude. They may be nearly coincident in value with the elastic limit of the metal, in which case the shape of the bar is not as stable as desired.

The preparation of the drilled and reamed holes used to define the extremities of the gauged lengths on the measured members is conducted in the manner described in "Notes on the Construction of Ordnance," April, 1887. Strain-gauge measurements made at that early date demonstrated their possibilities as an accurate method of investigation. The results were checked on work, published in June, 1886, having reference to changes in diameters at different depths in the walls of a thick hollow cylinder, in comparison with a mathematical analysis of the expected strains, a rigid check on experimental work which the strain gauge successfully met.

CLYDE T. MORRIS,* M. AM. SOC. C. E. (by letter).—In connection with the work which Mr. Fowler has described in this paper, there are several points which stand out as notable advances in structural engineering: Mr. Morris.

1st.—The determination of the existing dead load stress in a redundant member (the center top chord in this case) of a statically indeterminate structure, thus determining the true dead load stresses in all the members.

2d.—The re-distribution of the dead load stresses in the entire structure to help equalize the unit stresses, by changing the length of the redundant member and thus changing its dead load stress.

3d.—The adjustment, to a uniform initial stress, of the rod bracing by the use of the strain gauge.

The use of the strain gauge in measuring live load stresses in structures is not new, and its adaptation to the revision of this structure has been fully described by Mr. Fowler. There is no doubt that many bridges in use to-day, which are overloaded, could be reinforced so as to give service for many years to come, at a cost of but a fraction of the amount required for a new structure, if proper stress investigations were made and revisions worked out.

* Columbus, Ohio.

Mr. Morris.

A little more detailed description of the application of some of the strain-gauge measurements may not be out of place here.

Sway-Rod Adjustment.—The adjustment of the sway and lateral rods is an operation which is necessary every few years in all structures with adjustable bracing, and the results by the use of the strain gauge are so much more reliable than judgment by sounding with a hammer, that it should always be used in important structures.

In the preparation of the gauge holes for this work the extreme care used in the other parts of the structure was not found necessary, due to the fact that the whole operation for one pair of diagonals would be completed by one observer, with a single instrument, within a period of perhaps an hour. For the same reason no temperature corrections were made.

The gauge holes were made with a center punch ground to a slightly sharper angle than the points of the strain gauge. After a little experience these were found to be quite satisfactory for temporary use.

After the gauge holes were prepared, a set of initial readings would be taken on the two diagonals of a panel and then the turnbuckles slacked off until there was no stress in the rods. This could be determined by observing when the point was reached where further slackening produced no further change in the gauge reading. This reading was taken as a zero reading and then the turnbuckles were tightened until the desired reading on the gauge was obtained. A 20-in. Berry gauge was used. The tension put in the rods was about 7 000 lb. per sq. in. In tightening up the rods care was used to draw up both diagonals evenly so that the symmetry of the panel would be preserved.

The adjustment of the ninety-six sway rods occupied about four days. The writer took two bridge men with him to operate the turnbuckles. No staging was found to be necessary.

Floor-Beam Stresses.—Stress measurements were made with an 8-in. gauge, on both flanges of a floor-beam, at a number of points from the center out, and also on the curved brackets at the ends, and down the posts, to determine the variation in unit stress. Readings were also taken on the post below the highway deck to determine what effect would be carried down from the bending of the railway floor-beams. The results for the post U_2L_2 are given in Table 4, and show that below the highway floor, the unit stresses at Corners 1 and 2 are equal and those at Corners 3 and 4 agree within one division of the gauge. This proves that there was little or no transverse bending carried below the highway floor-beams. It was decided therefore that the reinforcement of the railway floor-beams and vertical posts could be determined by calculating the stresses due to floor-beam bending in the quadrangle frame formed by the two posts, the railway floor-beam, and the highway floor-beam. The variation in the measured unit stresses,

and those calculated by this method agreed very well. The measured unit stresses at the tops of posts U_2L_2 and U_6 L_6 are shown in the diagrams of Fig. 6. Mr. Morris.

The reinforcement of the floor-beams on the 115-ft. approach spans was also figured in this manner, although it is probable that the knee-braces there do not have as much stiffening effect on the floor-beams as the very heavy curved brackets of the main arch span.

ALMON H. FULLER,* M. AM. SOC. C. E. (by letter).—The writer has found much of interest in the Niagara Arch revision itself, but that interest has been greater, due to the fact that he went through the fundamental stress work as a thesis at Cornell University in 1898, just after the original structure was completed. He was told by the college authorities that very few structures of that nature had been rigidly analyzed and that the applications of the available theories were not generally understood. R. S. Buck, M. Am. Soc. C. E., makes the statement† that the sections used were means between those given by theory and those required for a three-hinged arch; the statement is repeated in different words by the late L. L. Buck, M. Am. Soc. C. E.‡ The computations in the writer's thesis brought out the fact (now generally recognized) that the successive approximations in stress work and design tend to distribute the material from the upper chords and web members to the lower chords. Mr. Fuller.

The situation in regard to the original design of the Niagara Railway Arch is that an excess of material was put into the upper chords and web members due to too few approximations in the stress work and that the light bottom chords of the original design were detected by the "eternal fitness of things" and increased as stated. The designers "builded better than they knew", as has already been stated by the author, and the structure contained more material than was needed to satisfy the specifications. This is one of the principal reasons why it was possible to increase the present capacity so readily, and, at the same time, it is the reason why such a close scientific study was justified and demanded. These facts were known by the writer and by the author before the revision was made, but it was not known in advance how the excess material was distributed. The determination of this distribution and the re-arrangement of stresses to meet it by means of the toggle adjustment were early recognized by the author and became leading features of scientific interest.

The author's suggestions in regard to wheel loads and column formulas are interesting and valuable. Previous discussion makes it evident that many able supporters will be found for both and just as evident that neither will be adopted without a struggle. Is it not per-

Mr. Fuller.

tinent to suggest, therefore, that the discussion makes it evident that both are live issues and that the interests of the profession will justify the appointment, by this Society, of special committees to consider them? It is gratifying to note that Mr. Schmitt's discussion also suggests committee action on the entire subject of bridge specifications.

In this connection, it is interesting to note Mr. Ammann's reference to secondary stresses. Very few men are as well qualified by ability and accomplishments as Mr. Ammann to discuss this perplexing subject. It seems surprising, therefore, to have him take the position that secondary stresses should be included only in the general factor of safety. Designers in general do not have the insight that Mr. Ammann does into the intensity and distribution of secondary stresses. Even if they did, it would certainly be more scientific and more practical as well, as experience is multiplied, to reduce the element of ignorance in the factor of safety and not only have the assurance that the higher unit stresses urged by the author may safely be used, but the added assurance that the material would be more logically distributed.

Mr. Belzner's inquiry concerning the respective accuracy of the Berry, Howard, and Fuller-West strain gauges is a reminder of Mr. Fowler's request to the writer to present the conclusions from the Niagara work and the subsequent comparison made at Lafayette College. The new instrument which Mr. Fowler has called the Fuller-West gauge, was developed in the shop of the Civil Engineering Department at Lafayette College, as a result of the Niagara work and the discovery of the "Last Word" dial. Such a large proportion of the development, as well as the excellent workmanship, was contributed by Mr. M. L. West, Mechanician for the Department, that the writer has designated it by the simpler and, he thinks, the more appropriate name of the West strain gauge. In speaking of the Howard instrument, Mr. Belzner says:

"In order to secure such results, which are absolutely essential, persistent patience and painstaking thoroughness, combined with good judgment on the part of the observer, are required until he gains perfect control of the instrument, after which he will experience little or no difficulty; and it is upon the observer that the value of such measurements will depend."

This also applies to both of the others, but apparently to a somewhat lesser degree. In other words, the limited experience of the writer in the use of the Howard gauge suggests that greater care in manipulation is required for the same precision than with either of the other instruments and that less speed is probable. He believes, therefore, that most observers would secure results of greater value in a given time with either of the other instruments. The writer prefers the Berry gauge for some work and the West gauge for other. In general, he, and the students he has broken in, will get results of

apparently the same precision in a shorter time with the West gauge; but no doubt those observations have been obscured somewhat by local prejudices. He feels, however, an added security in the work when one is used as a check against the other, and would feel just a little safer with both of them on an important piece of work. Mr. Fuller.

The indication, mentioned on page 1938, that the stress in tension members was greatest toward the center, was also noticed in a thesis investigation made under the direction of the writer by four seniors (Messrs. R. S. Gutelius, F. H. Krick, R. H. Moyer, and J. J. Waters), at Lafayette College in the spring of 1920. The bridge, in this investigation, was a multiple-span, double-track, riveted structure which had just been completed over the Delaware River between Easton, Pa., and Phillipsburg, N. J., by the Central Railway of New Jersey. The data are insufficient, of course, to conclude that these peculiarities in distribution always exist, but they suggest that they may be present and that attention might well be given to such detailing as will insure a more even distribution.

The thesis on the bridge mentioned also brings out the double secondary stresses, as illustrated for the Niagara Arch, on page 1936, but the variation is much smaller; in other words, the distribution is more nearly uniform. Does it not seem probable that the approach to uniformity of distribution in the newer structure is influenced favorably by the exceptionally rigid sway and lateral bracing? The values given on page 1936 for the fiber stresses in each plane at Niagara are evidently the averages of two values. It is apparent, therefore, that greater stresses exist on single corners, and it would be interesting, and, perhaps, valuable, to have them given.

The writer regrets that it has been impracticable for him to make the close study of Mr. Fowler's paper and his own notes which he had intended. As he gets further away from field and office work, the possibilities seem to grow, and he feels that the data gathered at Niagara have values even beyond those which have been brought out, and that they comprise a storehouse which may be drawn on as need develops for that particular kind of information.

CHARLES EVAN FOWLER,* M. AM. SOC. C. E. (by letter).—The writer has been much surprised to find how little use, comparatively, has been made of the strain gauge in bridge examination and revision. This is no doubt due to the facts that recent instruments of comparative simplicity have not been extensively tried out in practical work, and that the methods to be followed in order to obtain results are not understood to be only common-sense ones after all. One recent report on the strain-gauge measurements of a structure calls attention to the inaccuracy of readings due to rusting of the gauge Mr. Fowler.

* New York City.

Mr. Fowler.

holes, whereas the simple expedient of greasing them would have obviated the trouble.

The use of a mirror instrument is not necessary for the required practical accuracy, provided the observer has the necessary experience, backed up by the proper personality for careful and painstaking work. Although it is much easier for the engineer to tell the owner that his bridge is worn out or has been outgrown by the traffic, often he has no excuse for belonging to the Profession if he allows a good bridge to go into the scrap heap.

The analysis of railway bridge loading is valuable in indicating that it is probably now possible for an agreement to be reached with locomotive builders as to the future limiting weights; having in mind that this may not deter a railway manager from adopting a type of locomotive that is several degrees heavier than the traffic calls for. This is evident from one case where heavy Mallet locomotives were adopted for a low-grade line; when a Mikado with not more than 50 000 lb. on the drivers would have been sufficient.

The scheme of bridge loading proposed by the writer to take the place of the obsolete Cooper system has been somewhat misunderstood, and it was based on the data gathered by Messrs. Welty and Bouton for the American Railway Engineering Association, which were plotted in percentages, as shown in Plates XXXVIII and XXXIX. The calculations were made by including nearly thirty of the very heaviest locomotives of each type in use, and the writer in Table 1 refers to only four of these, or those giving the heaviest moments for each length of span. Thus, no "hand-picking" was done as Mr. Ammann seems to suppose, and it would seem that this scheme would answer the requirements of Dr. Waddell by simply plotting an equivalent load curve based on the same moments. Should any one have the temerity to build a locomotive giving heavier moments, the curve of moments or of equivalent loads could readily be revised from time to time. At any rate, the operating departments of the railways would know at once that no loads now in existence would be too heavy for bridges built for such a loading.

That many of the railway companies are not satisfied to start a design for a bridge with an initial error of from 10 to 15% in the live load stresses, is shown by the fact that Cooper's E-70 loading is being used by many since the adoption of E-60 loading in the new or 1920 American Railway Engineering Association specifications. This is certainly nearer the truth than E-60, being only 5% too light for short spans, but there will probably be considerable metal wasted in spans from 150 to 300 ft. long. Everything developed since 1885 in train loadings has shown the futility of the ultra-refinement of bridge calculation for wheel loads. Moving the locomotives used at

Niagara from having the first driver over the point, to the second driver, the third driver, or the fourth driver, gave little appreciable difference in truss stresses. Yet, with all said, it is certain that any engineer would soon discontinue the services of an assistant who constantly made direct errors in calculations of from 5 to 15 per cent.

Mr. Ammann's criticism with regard to impact allowance is well taken, from his point of view, but the speed on the Niagara Arch Bridge, had not been gradually decreased as the bridge became more heavily loaded. The speed on the Roebling Suspension Bridge had been limited in the contract with the railway company to 5 miles per hour, and this was still in force on the Arch. However, by sufferance, speeds up to 25 to 30 miles per hour had been allowed. Thus, it was a question as to how much of an increase beyond 5 miles per hour should be allowed in the new contract; and the readings showed that 17 miles was the maximum increase allowable if the bridge was to be brought up fully to E-60 capacity. Due to the condition of the structure and to yard conditions at both ends, it was out of the question to run up to test speeds that would determine the critical speed on the Arch. However, it was certain that at some speed beyond 24 miles, the impact would reach a maximum, then probably drop off, and in the writer's opinion possibly increase at a higher speed up to a second maximum. This would be dependent on many other things than speed, notably the type of bridge and panel length. The data on impact gathered by the American Railway Engineering Association are sufficient, no doubt, to make possible the derivation of a formula for the calculation of the critical speed for ordinary types of bridges, and it is interesting to note that a recent review of these data confirms the findings at the Niagara Arch, except that after reaching a maximum at about 50 miles per hour, the curve drops off and does not again rise for the quite high speeds of the tests. The Profession would be greatly benefited if these were developed fully and published. However, the formula given in the paper may be used with confidence in cases where it is necessary to determine the reduction in speed which is necessary on an old structure.

The writer does not agree with Mr. Ammann as to the omission of secondary stress from the total stresses. The great advantage in calculating the secondary stresses in a new truss design is to determine the worth of the scheme under consideration, and when they are excessive, the design should be modified, if possible. The writer has had numerous verbal discussions which confirm him in the belief that all stresses must be included in the total stresses and that one must gradually approach the elastic limit of the material used for unit stresses, but not go beyond, as some have advised—arguing that the secondary stresses would disappear by adjustment and readjustment.

Mr. Fowler.

However, by sufferance, speeds up to 25 to 30 miles per hour had been allowed. Thus, it was a question as to how much of an increase beyond 5 miles per hour should be allowed in the new contract; and the readings showed that 17 miles was the maximum increase allowable if the bridge was to be brought up fully to E-60 capacity. Due to the condition of the structure and to yard conditions at both ends, it was out of the question to run up to test speeds that would determine the critical speed on the Arch. However, it was certain that at some speed beyond 94 miles, the impact would reach a maximum, then probably drop off, and in the writer's opinion possibly increase at a higher speed up to a second maximum. This would be dependent on many other things than speed, notably the type of bridge and panel length. The data on impact gathered by the American Railway Engineering Association are sufficient, no doubt, to make possible the derivation of a formula for the calculation of the critical speed for ordinary types of bridges, and it is interesting to note that a recent review of these data confirms the findings at the Niagara Arch, except that after reaching a maximum at about 50 miles per hour, the curve drops off and does not again rise for the quite high speeds of the tests. The Profession would be greatly benefited if these were developed fully and published. However, the formula given in the paper may be used with confidence in cases where it is necessary to determine the reduction in speed which is necessary on an old structure.

The writer does not agree with Mr. Ammann as to the omission of secondary stress from the total stresses. The great advantage in calculating the secondary stresses in a new truss design is to determine the worth of the scheme under consideration, and when they are excessive, the design should be modified, if possible. The writer has had numerous verbal discussions which confirm him in the belief that all stresses must be included in the total stresses and that one must gradually approach the elastic limit of the material used for unit stresses, but not go beyond, as some have advised—arguing that the secondary stresses would disappear by adjustment and readjustment.

Mr. Fowler.

The column formula used for the Niagara Arch is well on the safe side, but the writer agrees with Dr. Waddell and Mr. Ammann that further study of the subject is advisable; nothing better can be done than has been done until a thorough study and review have been made of all the column tests made during the last thirty years. Indications are that the opinion expressed to the writer recently by George H. Pegram, Past-President, Am. Soc. C. E., is correct, that when this is completed we will return to a formula of the Gordon type as most nearly representing test values for unit stress. This seemingly accords with the findings of O. E. Hovey, M. Am. Soc. C. E., with regard to the report of the Special Committee on Steel Columns and Struts of the Society. Recent specifications do not do justice to the American bridge engineer, who has long prided himself as being thoroughly scientific and not in favor of compromises.

The point made by Mr. Ammann with regard to column design is well taken, and much could be gained by more study in the designing and detailing of columns. The recent column tests by the U. S. Bureau of Standards emphasize the fact that a great difference in column strength is obtained in the arrangement of lacing, as was pointed out long ago by John E. Greiner, M. Am. Soc. C. E., in his study of secondary stresses in columns due to the arrangement of lacing bars. The fact noted by Mr. Schmitt with regard to the Niagara Bridge design being a generation ahead of its time, is especially true of the columns and built tension sections and their detailing, and they are entitled to much study by the present generation of designers.

The comparison of the strain gauges used at the Niagara Bridge was not carried far enough to give conclusive data in answer to Mr. Belzner, but without any reflection on either of the three types that were tried out, it may be said that although the Howard gauge is highly satisfactory for static work as regards final results, it is not at all possible to use it where moving loads are constantly passing over a bridge, nor for impact readings. Neither is it as easy to use as either of the other types. The Berry gauge was highly satisfactory for the dead load readings and for the static live load, but for impact work the vibration of the needle of the Ames dial made the readings too large, which, of course, was on the side of safety. The Fuller-West instrument was, in the writer's opinion, the best for all classes of work, and the only one that was really accurate for impact, as there was no disconcerting vibration of the needle of the "Last Word" dial. For the work done it was more satisfactory than a deflectometer.

The great care necessary in drilling the holes for the gauge points and in holding the strain gauge perpendicular to the member was a vital point, and necessitated a large number of check readings. The new scheme devised by Professor Fuller's mechanician, Mr.

West, is one of the greatest improvements yet made for strain gauge work. This consists in drilling the small holes and then setting into them a small ball-bearing ball, as in Fig. 24. The leg of the instrument, instead of being pointed, has a conical recess to set on the projecting half of the ball. The instrument thus gives perfect readings when the legs are considerably out of plumb, and thus a great number of check readings are not required. Mr. Fowler.

Early morning readings before the sun heats up the steel, are not necessary if proper temperature readings are made and the corrections calculated. In fact, it is next to impossible to get test trains except during regular working hours. The advisability of permanent gauge points on important structures mentioned by Mr. Howard should be taken to heart by all builders of big bridges, as the cost would be small, and the gain to the owner beyond question, to say nothing of the scientific data that would eventually be gained. The cost need not exceed $2 per pair of points even if the large holes and the tapping

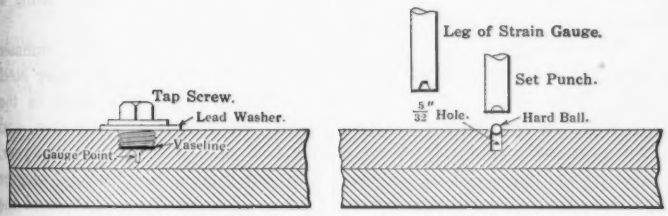

FIG. 24.

are done with a breast hand drill; thus, the points on 150 members of a long span would cost about $300. (Fig. 24.)

The many points raised by Mr. Schmitt are quite vital in the consideration of general and detail design. There can be no question but that the designer in endeavoring to make up his sections for easy future reinforcement will get a much better average make-up of sections; and he should also endeavor to design members that can easily be repainted and re-riveted in the field. One vital point, as brought out by results at the Niagara Bridge, is that all plates and shapes should be thickened about $\frac{1}{32}$ in. for each 20 years of the proposed life of a structure; and where there is apt to be excessive corrosion, then this amount should be doubled. Thus, the exposed top plates or angles of beams and stringers, and the horizontal cover-plates or exposed angles should be increased more than $\frac{1}{8}$ in. for an assumed life of 40 years. The extra good care given the Niagara Arch was very exceptional.

Mr. Fowler.

The methods used in the placing of reinforcing on members subjected to dead load stress were certainly superior to any such method as heating which might injure the steel and could not possibly be uniform throughout the length of a member, nor during the time required for the operation. The erratic distribution of stress over the cross-section of a truss member serves to make uncertain the realization of the computed unit stresses, and points anew to the necessity for a careful consideration of all kinds of secondary stresses. The writer cannot agree that the calculation of the stresses for such a two-hinged arch or other form of indeterminate structure is of necessity obviously correct, or as surely correct as for a simple structure, and it is certainly making assurance doubly sure to measure the dead load stresses as was done initially at the Hell Gate Arch and, latterly, at the Niagara Arch. The general run of the results of the latter for static live load was corroborative of the dead load stresses in other members than the center top chord where the dead load stress was actually measured. This could easily have been proven by using a toggle on some other member, at, however, a much greater cost.

The examination of the copper steel salt-water floor this summer (1920) has happily confirmed the reasons for the use of copper steel and of the enamel coating. The repair of some bad spots in the coating did not comprise more than about 5% of the top area, and was practically the only maintenance cost on the bridge for the year. The copper steel, where exposed, had not rusted to any such degree as is usual with ordinary carbon steel. The recent publication of the good condition of copper steel tie-plates, as compared with ordinary tie-plates, was another pleasing confirmation of the wisdom of the experiment. The cost of renewing some of the troughs, if necessary some years from now, will be only a fraction of the cost of renewing top flanges of beams and stringers at a cost of probably $30 000. The low first cost of such a floor and the saving in dead load on the structure should recommend a similar design for new bridges.

The question as to the rod bracing allowing more vibration in the Arch than would be the case with stiff bracing was carefully studied. It is true that the adjustment of the rods by using the strain gauge did add to the stiffness, as some of them were stressed to the elastic limit and undoubtedly gave more or less under lurching trains, but there was a general swing to the long rods which was accentuated by the inertia of the pin and eight loop eyes at the center crossing. The new stiff bracing, of course, was made heavy enough to allow for the future four-tracking of the bridge, but while the gusset connections may induce some secondary stresses in the truss members, it is also true that in the final analysis they serve to shorten in a

degree the length of the main members and to bind the entire structure more firmly together. Mr. Fowler.

The slowness of the center top chords to take full stress after the change of the shims certainly was due largely to the compressive stress that was taken by the tight stringers, by the 100-lb. rails with tight joints, and, lastly, to a certain readjustment of the center bottom joints, where the gussets had been curved out and some of the rivets cut out, as was shown by the check strain gauge readings. Certain it must be that there were infinitesimal elastic adjustments at other truss joints, and this may still be slowly going on.

The riveting done during 1918 and 1919, referred to by Mr. Bentham, was not because of overload, or train vibration, except as found in some joints in the northwest quarter of the arch, which gets more traffic due to yard switching, but was largely due to poor field riveting when the bridge was built. This was not to be avoided when driving 1-in. rivets by hand, as had to be done in 1896-97. Had they been tested with an 8-lb. sledge, as the writer once knew an inspector to do (!), it could have been found at the time. Redriving them with long gun air riveters, drew the plates more firmly together and loosened adjacent rivets to the extent that in some cases all of the 250 or more rivets in a joint would have to be redriven. The low unit stress first used, 6 500 lb. per sq. in., had prevented the joints from working. Many of the hand-driven rivets had never been upset to fill the holes, and were rusted inside from end to end, although this did not show outside, around the heads, the rivet heads in all cases being tight against the member or plate.

The writer has already replied to Mr. Ammann and others in regard to the query of Mr. Lang, pointing out that the Welty-Bouton data prove more conclusively against the retention of Cooper's loadings, than for their continuance as the standard. The writer has seen too many such questions answered by "time" in the past thirty years, not to await "time's" verdict in this case.

The wasting away of the plates from salt-water corrosion was quite uniform over the entire surfaces, whole layers or laminations being removable; for angles, however, it was in patches and depressions, but also over the entire exposed surfaces.

The careful reader will certainly find the matter of highway loads fully covered under the head of "Highway Floor." The 15-ton truck was of the standard type as to the spacing of axles, wheels, and loads. The writer is not aware of any statement to the effect that the bridge had been revised for E-80 loading, having been made in the paper.

Replying to Mr. Bentham's query about keeping trains going: Only one track was removed at a time; when the first track was complete, traffic was shifted and the other track torn up. The only work extend-

Mr. Fowler.

ing across under the track in use was the replacement of the top floor-beam cover-plates. This reduction in strength of beams was made up by shoring and slow speed of trains.

The writer would feel sure, after the experiences with salt-water corrosion at Niagara, that it would be a reasonably simple matter to correct the effects of salt-water corrosion on the lower parts of the Forth Bridge, and to protect it against further corrosion. Whether or not the rusting has been severe enough seriously to endanger the structure would be interesting to know, but it is to be presumed that the data regarding the original design of the bridge, which have never been made public, would make this a matter to be easily determined.

The whole of the Niagara Bridge investigation and revision, and the discussion of this paper, makes one quite certain that engineers cannot now stop, self satisfied, with the present status of bridge design. There is little incentive, it is true, for anything except machine-made plans; but with the data available from which to formulate a real specification why is it not incumbent upon the Society to fix a standard as high as the materials specifications of the American Society for Testing Materials?

ARCHED DAMS.

By B. A. Smith, M. Am. Soc. C. E.

With Discussion by Messrs. Chauncy Wernecke, L. R. Jorgensen, William Cain, and B. A. Smith.

Synopsis

A solution of the problem of arch dam analysis is offered which, although not free from objection, avoids the obvious defects of the ordinary cylinder theory. These defects are, that, by the latter theory, the arch thrust is a maximum at the base of the dam where, as a matter of fact, it must vanish and that it vanishes at the crest where, in any ordinary case, the deflection is greatest and, as a consequence, the stress due to the arch thrust must be a maximum. Two cases are dealt with: (1) A complete cylindrical dam or tank of uniform thickness throughout; (2) a complete cylindrical dam or tank of uniformly varying thickness from crest to base. The mathematical investigation of these cases is given in Appendix I. Case 1 is found to be included in Case 2.

It is shown in Appendix II that, provided we neglect the twist in the material arising from the base being fixed while the cylinder is deformed by the water pressure, we can use the solutions obtained for the complete cylinder as an approximation to the solution for the deepest part of a dam built in a valley of any form, provided we replace the ordinary Young's Modulus for the horizontal thrusts by a modulus two-thirds as great. The effect of temperature is con-

sidered, and it is demonstrated by a numerical example in Appendix IV that the stresses due to variations of temperature may be considerably greater than those due to the water pressure.

Tables of Michell's functions are given, which enable the solution of any problem on the design of arched dams of wedge-shaped cross-section, the up-stream surface being a vertical cylinder of constant radius, to be made. The chief labor involved is the solution of a set of four simultaneous equations to determine four arbitrary constants which enter into the expression for the displacement of any point in the vertical generators of the cylinders, but with a 6 or 8-figure calculating machine this can be done in about an hour.

A remarkable feature of Michell's functions is the balance which subsists between them leading to very small resultants when the functions are combined in the course of the work. This renders it necessary to exercise care in using them; in particular it will be found necessary to retain six or seven significant figures in the arbitrary constants, otherwise we shall be led to quite erroneous results. A perusal of the numerical work in Appendix III will show this clearly.

Although at first sight the tables appear to be limited to a height of 30 ft., it will be found that this is not really the case, the numbers 1 to 30 in the tables are merely like the ordinary numbers in a table of logarithms, and the height may be 200 ft., or even more. The limitation of the investigation to the two cases of uniform thickness and a truncated wedge-shaped cross-section will, it is hoped, be viewed with leniency, when account is taken of the somewhat laborious nature of the investigation even in these two comparatively simple types of arched dams.

The Cylinder Theory.

A recent paper by H. Hawgood, M. Am. Soc. C. E., on the Huacal Dam, Sonora, Mexico,* indicates that the subject of the design of arched dams is not yet exhausted. The usual procedure hitherto has been to assume that the arch thrust is given by the expression†:

$$T = p\,R$$

* *Transactions*, Am. Soc. C. E., Vol. LXXVIII (1915), p. 564.

† *Transactions*, Am. Soc. C. E., Vol. LXXVIII (1915), Table 1, p. 567.

in which

p = the pressure, in pounds per square foot, at the section considered;

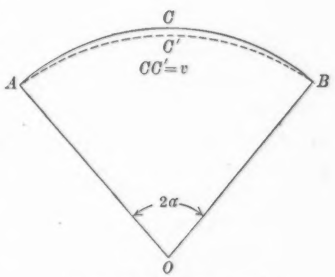
R = the radius of the up-stream face, in feet;

T = the arch thrust, in pounds per foot height of the dam at the given section.

It is, however, generally recognized by engineers that this expression can only give the thrust at points so far above the base that the arch can deflect sufficiently to allow the material to come into compression. In the case of the Huacal Dam, for example, the radial displacement near the base would have to be of the order of $\frac{1}{8}$ in. in order to allow the calculated arch thrust to exist. An elastic movement of the foundation rock of this magnitude is hardly conceivable. The assumption that the base is rigidly fixed is probably a much nearer approximation to the actual conditions.

Proposed Modification of the Cylinder Theory.

This paper is an attempt to carry the approximation of the cylinder theory a step further by taking account of the shear across a horizontal plane and the corresponding bending moment about a horizontal tangent to the cylinder.



PLAN OF SEGMENTAL DAM
Fig. 1.

First, consider a complete cylinder symmetrically deformed so that the displacement of every point is radial. It is clear that, in this case, there will be no shear across vertical axial planes, and as a consequence there will be no bending moment about the vertical generators; that is, in the case of the complete cylinder, bending as a horizontal arch does not occur.

Segmental Dams.

Next, consider a segment of the cylinder $A\ C\ B$, Fig. 1, between two vertical generators at A and B, respectively, subtending an angle $A\ O\ B = 2\ \alpha$ at the axis O, and suppose this segment is free to slide on the base and is merely supported at the ends A and B so that the bending moment vanishes at each of these ends. Then,

assuming that the bending moment vanishes throughout and that the segment is subjected to a uniform compressive stress (arch thrust) throughout its length so that the elastic compression, f, is constant throughout, the segment deforms to the shape $A\ C'\ B$ and, as is shown in Appendix II, the displacement $C\ C'$ $(= U)$ of the center of the segment is given by

$$U = \frac{f\ R\ \alpha\ (1 - \cos.\ \alpha)}{\sin.\ \alpha - \alpha \cos.\ \alpha}$$

where

f = the elastic compression of the material; that is, the ratio of the contraction of any given length under compression to the original length of that portion;

R = the radius of the cylinder;

2α = the angle $A\ O\ B$.

If $2\ \alpha$ is less than $\frac{2\ \pi}{3}$, or 120°, there can be written, approximately,

$$U = \frac{3}{2} f\ R$$

which is independent of α.

This means that the radial displacement U at C, the center of the segment, $A\ C\ B$, supposed to be fixed in position at the abutments A and B, though free to turn about these points, is the same as it would have been if $A\ C\ B$ formed part of a complete cylinder, subject to the same stress, the value of Young's Modulus E for which is two-thirds of that of the actual material.

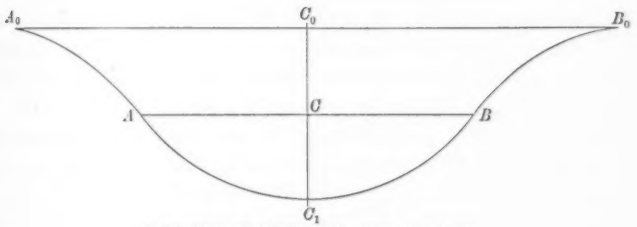
It may be mentioned, to anticipate the objection being taken, that unless extraordinary precautions are taken to fix in direction the ends of the arch, A and B, there will be deflections at these points which will correspond very nearly to the deflections due to no bending moment at A and B.

Dams Constructed in Valleys of Any Profile.

In order to pass from the ideal case to the actual one, namely, a dam built in a valley of any profile, the twist in the surface which occurs when the base, instead of being free to slide, is fixed throughout, is neglected. If this is done, $A\ C\ B$, Fig. 2, may be regarded as any horizontal section of a dam of which $A_0\ C_0\ B_0$ is the crest and $C_0\ C\ C_1$

the central vertical generator so that $A_0\ A\ C_1\ B\ B_0$ is the profile of the valley which, under the conditions premised, may be of any shape whatever, as long as it is approximately symmetrical. As shown in Appendix II, and subject to the limitations there given, the radial displacement of any point C of the central vertical generator $C_0\ C\ C_1$ will then be the same as if that generator formed part of a complete cylinder the value of Young's Modulus for which is two-thirds of that of the actual material of the dam.

The solution obtained for the complete cylinder is thus applicable (subject to the reservations mentioned above) to the case of any ordinary arched dam, the value of Young's Modulus being taken as two-thirds of its value for the material of which the dam is built.



ELEVATION OF SEGMENTAL DAM IN VALLEY

FIG. 2.

LIMITATION OF SOLUTIONS TO TWO TYPES OF DAM.

Two cases are here considered: (1), a cylindrical dam or tank of uniform thickness throughout; (2), a cylindrical dam of finite crest width and of uniformly varying thickness from crest to base.

The difficulty of obtaining a solution of the equation of equilibrium of the material in other cases must be pleaded in excuse for no attempt being made at a general solution applicable to dams of any cross-section; the simple cases considered are troublesome enough. The solution of the first case, the cylindrical dam of uniform thickness, results quite simply in terms of known functions, circular and hyperbolic. The solution of the second case is obtained in series. Four different series each of which satisfies the equation of equilibrium are required; these are given in algebraic form, together with tables for the values of each of the functions and their first three derivatives, which are all required to satisfy the boundary conditions at the

crest and at the base of the dam. These functions will be referred to as Michell's* functions.

It is shown that the solution of the fundamental equation can be formally expressed in terms of Bessel's functions, but as the functions involved have complex arguments it is considered preferable to leave the solution in terms of Michell's functions, which involve only a real argument. The solution in terms of Bessel's functions, however, is useful as it permits the extension of the tables by using the "semi-convergent" expressions, and this makes it possible to deduce the solution for the uniform dam from the case where the thickness is variable.

An equation corresponding to the fundamental equation of Case (2) for a particular case, namely, when the section is a triangle with its crest at the water level, is given by H. Lorenz†, but as this solution is of very limited application and as only two solutions of the four series of the fundamental equation are given, and then only in series form, it cannot be regarded as a complete solution of the problem.

The solution obtained for Case (1) shows that the bending moment rapidly dies out as we leave the base of a dam or tank of uniform thickness, whether the base is fixed in direction or merely simply supported, and that at a height above the base equal to three or four times the thickness of the dam the ordinary cylinder formula, $T = p\,R$, applies quite nearly enough. This statement must not be taken to indicate that the bending moment near the base can be disregarded, for this cannot be done altogether, but it shows the great assistance given by the arch in supporting the load on the dam.

Temperature Effect.

The effect of temperature changes on the stresses is considered, and it is shown that a very moderate range of temperature will give rise to stresses considerably greater than those due to the water pressure. As a consequence, it appears that, if practicable, a concrete dam should be built at a time when the temperature is well below the mean temperature of the locality, for if this is done the effect of a rise of temperature is to enhance the arch effect, and it may even cause the dam to deflect up stream against the water pressure. This

* These functions are here published for the first time.

† "Lehrbuch der Technischen Physik", Vol. IV, p. 618.

was found to happen in the case of the Wooling Dam, to which these calculations were first applied.

A similar phenomenon is suggested by the observations of the deflections of the Barren Jack Arch Dam shown in Fig. 6 of the paper* by Mr. Hawgood.

The Arguments of Michell's Functions.

Attention should be called to the fact that the arguments x in the tables of Michell's functions are not actual heights but are mere numbers like the arguments in a table of logarithms. The relation between x and the actual depth z below the origin, which is taken to be at the intersection of the up-stream and down-stream faces of the dam, is given by

$$z = a\,x$$

where

$$a^2 = \frac{1}{12}\,c^2\,R^2\,\frac{E_1}{E_0}$$

in which

c = the tangent of the angle between the up-stream and down-stream faces of the dam, in a vertical axial section;

R = the radius of the cylindrical up-stream face;

E_1 = Young's Modulus for the vertical forces;

E_0 = Young's Modulus for the arch thrust.

In the case of the complete cylinder, E is the ordinary value of Young's Modulus. In the case of the segmental dam, E_0 becomes $\frac{2}{3}E_0$. The value of E_1 depends on the vertical reinforcement. If p is the ratio of area of steel reinforcement to concrete, then

$$E_1 = E\,(1 + 15\,p)$$

where E is the ordinary Young's Modulus for concrete for the vertical reinforcement. For steel, $E_1 = 30 \times 10^6$ lb. per sq. in. $= 15 \times E$.

For example, if $p_1 = 2\%$ and $E = 2 \times 10^6$ lb. per sq. in. and $p_0 = 1\%$ for the horizontal reinforcement,

$$E_1 = 2 \times 10^6\ (1 + 15 \times 0.02) = 2.6 \times 10^6$$
$$E_0 = 2 \times 10^6\ (1 + 15 \times 0.01) = 2.3 \times 10^6$$

The fact that the dam is segmental does not affect E_1, in calculating which the ordinary Young's Modulus is used. Suppose, for

* *Transactions*, Am. Soc. C. E., Vol. LXXVIII (1915), p. 578.

example, a segmental dam of 200 ft. radius with the up-stream face vertical and the batter of the down-stream face 1 in 6, so that $c = \frac{1}{6}$, and with 2% vertical reinforcement and no horizontal reinforcement. There is obtained

$$E_1 = 2.6 \times 10^6 \text{ lb. per sq. in.}$$
$$E_0 = 2.0 \times 10^6 \text{ lb. per sq. in.}$$

and since the dam is segmental, replace E_0 by $\frac{2}{3}\ E_0$, that is, by $\frac{2}{3} \times 2.0 \times 10^6$, and

$$a = \frac{1}{6} \times 200 \times \sqrt{\frac{1}{12} \times \frac{2.6 \times 10^6}{\frac{2}{3} \times 2.0 \times 10^6}}$$

$$= \frac{200}{6} \times \sqrt{\frac{1}{12} \times \frac{3}{2} \times 1.3}$$

$$= 13.5, \text{ say.}$$

Now, suppose that the crest width of the dam is 4 ft. 6 in. and its depth 202 ft. 6 in. (corresponding to a dam about 200 ft. deep). Since the batter is 1 in 6, the origin is at a height $6 \times 4.5 = 27$ ft. above the crest. At crest level $z = z_0 = 27$ ft. and

$$z = a\,x = 13.5\,x$$

hence

$$x_0 = \frac{27}{13.5} = 2.0$$

At the base, $z = z_1 = 27 + 202.5 = 229.5$ ft., and therefore

$$x_1 = \frac{229.5}{13.5} = 17.0$$

and the tabular values to be used are those corresponding to $x = 2$ at the crest, and to $x = 17$ at the base.

The range covered by the tables will be found to be sufficient for most practical purposes. If it is desired to go beyond the tables, it is suggested that the semi-convergent expressions be used in preference to the series, which become unmanageable at about $x = 30$.

Proposed Method of Design, Using Michell's Functions.

It is suggested that as a convenient method of design the following procedure be adopted:

1.—Determine the maximum flood height above the crest of the dam $= h$, say.

2.—Assume that the pressure at any depth d below the crest is

$$p = w\,(d + h)$$

where $w = 62.5$ lb. per sq. ft. per foot depth (which is of course the same as the weight of 1 cu. ft. of water).

h = height of flood level above crest, in feet.

d = depth of the given point below the crest, in feet.

This will give pressures near the crest slightly in excess of the actual pressures, but this error may be disregarded.

3.—Fix the maximum compressive stress (arch thrust) allowable in the material = K lb. per sq. ft., say, and determine the corresponding thickness of the dam by the ordinary cylinder formula

$$T = p\,R$$

where T = the resultant ring thrust per foot height.

p = the pressure, in pounds per square foot, as given above.

R = the radius of the arch.

The smaller R is, of course, the smaller T will be and the more effective the arch action. If t is the thickness of the arch, in feet, then

$$T = K\,t = p\,R$$

4.—Fix the minimum safe thickness at the crest of the dam in view of possible injury by floating timber or other bodies, say, t_0 ft. Then, if the thickness is to vary uniformly from t_0 at the crest to t_1 ft. at the base in the depth, D,

$$c = \frac{t_1 - t_0}{D}$$

5.—Decide whether the base of the dam is to be rigidly built into the foundation rock by means of steel reinforcing bars sunk well into the rock below, that is, encastrée, or whether the base is to be simply supported by the pressure of the rock down stream against the down-stream face of the dam. The former method will ensure a water-tight base, but can only be adopted when the rock is quite solid. If the latter method is adopted, observe that the vertical generators of the cylinder will deflect down stream under the water pressure, and cause the base of the dam to lift off its seat on the up-stream side causing liability to leakage under the seat which must be provided against by layers of clay and sand or otherwise according to judgment. If it is decided

that the base shall be encastrée, the conditions to be satisfied at the base are:

(1), the radial displacement must be zero, that is, $u = 0$;

(2), the generating lines of the cylinder must remain fixed in direction, that is, $\frac{d\,u}{d\,x} = 0$.

If the base is simply supported, the bending moment at the base vanishes and, as before, the radial displacement must vanish, that is, (1) $u = 0$; and (2) $\frac{d^2\,u}{d\,x^2} = 0$. At the crest the boundary conditions are the same in either case, namely, the bending moment and the shear, both of which are due to the action of the material above the section or that below it, must vanish, since there is no material above the crest, that is, at the crest

$$\frac{d^2\,u}{d\,x^2} = \frac{d^3\,u}{d\,x^3} = 0$$

These four conditions give rise to four equations among the four arbitrary constants which enter into the solution. When these four constants are determined it is possible, by means of the tables, to find the displacement and consequently the arch thrust at a series of points, also the bending moment, the shear and, if necessary, the deflection, although this is of no interest to us except at the base of the dam. When the bending moments have been determined at the points corresponding to the integral values of x given in the tables, a smooth curve can be drawn through these points to give nearly enough the bending moment at any point of the dam. The necessary reinforcement can then be found by the usual rules.

A remarkable feature of the solution is the smallness of the resulting bending moment compared with the magnitude of the four component terms which contribute to it. An example of the numerical calculations is given in Appendix III.

6.—Determine the temperature range to which the dam will be subject and estimate as nearly as practicable the amounts by which the maximum and minimum temperatures vary from the mean temperature during construction. Let e = the coefficient of expansion of the concrete, or 0.0000055 per degree Fahrenheit, say (about $\frac{3}{4}$ in. per chain for 100° Fahr., as against about $\frac{1}{2}$ in. per chain for 100° Fahr. for steel). For satisfactory construction a nickel-iron alloy having

the same coefficient of expansion as concrete, is a desideratum, as this would minimize the internal stresses due to unequal expansion and contraction of the iron and the concrete. Suppose θ is the maximum difference of temperature in degrees Fahrenheit to be expected from the mean temperature observed during construction, regarded as plus if above this mean and minus if below it. As before, let R be the radius of the dam. If now the dam, supposed to be empty, is free to expand throughout, the displacement at any point will be, in feet,

$$v = - e \theta R$$

the minus sign being used to indicate that the points considered move away from the axis. If, after this expansion, the base is now forcibly displaced toward the axis through the distance, v, the generators being held fixed in direction $\left(\frac{d u}{d x} = 0\right)$, if the base is encastrée, or allowed to deflect so that the bending moment vanishes $\left(\frac{d^2 u}{d x^2} = 0\right)$, if the base is simply supported. In either case, the conditions at the crest are that the bending moment and the shear both vanish; that is,

$$\frac{d^2 u}{d x^2} = \frac{d^3 u}{d x^3} = 0$$

If these four conditions are satisfied the dam is clearly in the same condition as if the base had been fixed while the temperature rose by the amount θ.

This again gives rise to four simultaneous equations for four new arbitrary constants. The coefficients on the left-hand side of the equations are the same as those which were used in determining the constants for the water-pressure equations, so that the labor of the solutions is lightened in this case. The stresses due to the temperature are of course to be superposed on those due to the water pressure. An example of the numerical work is given in Appendix IV.

APPENDIX I.

INVESTIGATION OF STRESSES IN CYLINDERS

Explanation of Symbols.

Consider the origin O to be at the top-water level (flood level) of the dam in cases where the thickness is uniform and at the intersection of the up-stream and down-stream faces when the dam is of triangular section, and consider the axis of Z vertical downward. Let

T = ring thrust per unit depth at any point P at depth z below the origin, reckoned positive when compression;

F = the resultant traction or shearing force per unit length along the dam at P exerted by the material above P on that below P, reckoned positive when this traction is exerted toward the axis of the cylinder;

M = the couple about a horizontal tangent at P per unit length of the dam, reckoned positive when the bending tends to make the generators of the cylinder concave toward its axis.

u = the displacement, along the radius, of a point P on the cylindrical surface, reckoned positive when toward the axis of the cylinder. (Strictly speaking, these should refer throughout to the neutral surface, but it is simpler to deal with the up-stream cylindrical surface. So long as the dam is thin the error is not worth considering);

$\frac{d\,u}{d\,z}$ = the inclination of the generator to the vertical, reckoned positive when the lower part is inclined toward the axis;

$\frac{d^2\,u}{d\,z^2}$ = the curvature of the generator at P after strain, reckoned positive when the concavity is toward the axis of the cylinder;

t = the thickness of the dam at P;

I = the moment of inertia of a horizontal section of the dam at P, of unit length along the cylinder, or $I = \frac{1}{12}\,t^3$;

E_0 = Young's Modulus for the horizontal direction. If p_0 is the ratio of the area of horizontal reinforcement to the area of the concrete in a vertical section, assuming that Young's Modulus for steel is 15 times as great as for

ordinary concrete for which it has the value E, then $E_0 = E\ (1 + 15p_0)$;

E_1 = Young's Modulus for the vertical direction. If p_1 is the ratio of the area of vertical reinforcement to the area of concrete in a horizontal section, then, as above, $E_1 = E\ (1 + 15p_1)$;

C_1 = the rigidity of a vertical slab of unit length along the dam; neglecting the change of curvature in the horizontal plane, $C_1 = E_1 I = \frac{1}{12}\ E_1\ t^3$;

p = the water pressure, in pounds per square foot, at $P = w\ (d + h)$, where w is the weight of 1 cu. ft. of water = 62.5 lb., d the depth of the point P below the crest of the dam and h the flood height;

R = the radius of the cylindrical up-stream surface of the dam;

c = the tangent of the angle between the up-stream and down-stream faces.

a = a factor connecting vertical distances with the arguments of Michell's functions defined by Equations (31) and (33) following:

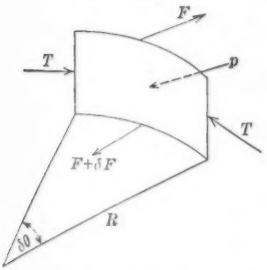


DIAGRAM OF FORCES ON AN ELEMENT

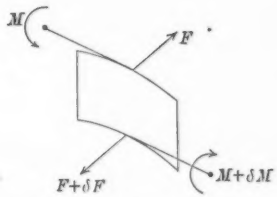
FIG. 3.



SHEARING FORCES AND COUPLES ON AN ELEMENT

FIG. 4.

EQUATIONS OF EQUILIBRIUM

Considering the equilibrium of a small curved rectangular element of height δz and width $R\,\delta\theta$, there is obtained (see Figs. 3 and 4), for the forces

$$(F + \delta F)\ R\,\delta\theta - F\,R\,\delta\theta - T\,\delta z\,\delta\theta + p\,R\,\delta\theta\,\delta z = 0$$

and for the couples

$$(M + \delta M)\ R\,\delta\theta - M\,R\,\delta\theta + F\,R\,\delta\theta\,\delta z = 0$$

Hence, dividing out by $R\,\delta\,\theta\,\delta\,z$

$$\frac{d\,F}{d\,z} - \frac{T}{R} + p = 0 \quad \ldots\ldots(1)$$

$$\frac{d\,M}{d\,z} + F = 0 \quad \ldots\ldots(2)$$

and for the equation connecting the bending moment with the change of curvature, as usual

$$M = C_1 \frac{d^2\,u}{d\,z^2} \quad \ldots\ldots(3)$$

neglecting the bending about the vertical generators, which is very small.

Again, the equation connecting the displacement with the ring thrust in the complete cylinder is

$$T = \frac{E_0\,t}{R} \times u \quad \ldots\ldots(4)$$

and in the case of a segmental dam (see Appendix II),

$$T = \frac{2}{3}\,\frac{E_0\,t}{R} \times u \quad \ldots\ldots(5)$$

Eliminating F between Equations (1) and (2)

$$\frac{d^2\,M}{d\,z^2} + \frac{T}{R} = p \quad \ldots\ldots(6)$$

Substituting for M from Equation (3) and for T from Equation (4), for the case of the complete cylinder

$$\frac{d^2}{d\,z^2}\left(C_1 \frac{d^2\,u}{d\,z^2}\right) + \frac{E_0}{R^2} \cdot t\,u = p \quad \ldots\ldots(7)$$

and in the case of the segmental dam

$$\frac{d^2}{d\,z^2}\left(C_1 \frac{d^2\,u}{d\,z^2}\right) + \frac{2}{3} \cdot \frac{E_0}{R^2}\,t\,u = p \quad \ldots\ldots(8)$$

Equations (7) and (8) are identical except that in Equation (8) the value $\frac{2}{3}\,E_0$ is used instead of E_0; that is, for the horizontal stresses a modulus equal to two-thirds of the ordinary Young's Modulus is applied.

CASE 1.—Dam of Uniform Thickness.

For the case of a dam of uniform thickness, t is constant, so that Equation (7) becomes

$$\frac{d^4\,u}{d\,z^4} + \frac{E_0\,t}{C_1\,R^2}\,u = \frac{p}{C_1} \quad \ldots\ldots(9)$$

or calling

$$\mu^4 = \frac{E_0\, t}{C_1\, R^2} = 12\, \frac{E_0}{E_1}\, \frac{1}{t^2\, R^2}$$

Equation (9) may be written in the form

$$\frac{d^4\, u}{d\, z^4} + \mu^4\, u = \frac{p}{C_1} \ldots\ldots\ldots\ldots\ldots\ldots (10)$$

Now, if p involves no power of z above cubes (in this case $p = w\, z$, so that it only involves the first power of z), the particular integral of Equation (10) is

$$u = \frac{p}{\mu^4\, C_1} = \frac{p\, R^2}{E_0\, t} = \frac{w\, R^2}{E_0\, t}\, z \ldots\ldots\ldots\ldots\ldots (11)$$

for this makes $\frac{d^4\, u}{d\, z^4} = 0$ and, therefore, satisfies Equation (10).

There must now be found a solution of

$$\frac{d^4\, u}{d\, z^4} + \mu^4\, u = 0 \ldots\ldots\ldots\ldots\ldots\ldots (12)$$

involving four arbitrary constants (the complementary function).

The auxiliary equation is

$$m^4 + \mu^4 = 0 \ldots\ldots\ldots\ldots\ldots\ldots (13)$$

from which

$$m^2 = \pm\, \mu^2\, \sqrt{-1} = \pm\, i\, \mu^2$$

hence

$$m = \pm\, \mu\, \sqrt{\pm\, i} = \pm\, \frac{\mu}{\sqrt{2}} (1 \pm i)$$

the four roots of Equation (13) are therefore

$$m_1 = +\, \frac{\mu}{\sqrt{2}} (1 + i)$$

$$m_2 = -\, \frac{\mu}{\sqrt{2}} (1 + i)$$

$$m_3 = +\, \frac{\mu}{\sqrt{2}} (1 - i)$$

$$m_4 = -\, \frac{\mu}{\sqrt{2}} (1 - i)$$

so that

$$m_1^4 = m_2^4 = m_3^4 = m_4^4 = -\, \mu^4 \ldots\ldots\ldots\ldots\ldots (14)$$

The complementary function is therefore

$$u = A^1 e^{m_1 z} + B^1 e^{m_2 z} + C^1 e^{m_3 z} + D^1 e^{m_4 z} \quad \ldots\ldots\ldots(15)$$

This is easily verified by differentiating Equation (15) four times

$$\begin{aligned}\frac{d^4 u}{d z^4} &= m_1^4 A^1 e^{m_1 z} + m_2^4 B^1 e^{m_2 z} + m_3^4 C^1 e^{m_3 z} + m_4^4 D^1 e^{m_4 z} \\ &= -\mu^4 [A^1 e^{m_1 z} + B^1 e^{m_2 z} + C^1 e^{m_3 z} + D^1 e^{m_4 z}] \\ &= -\mu^4 \times u\end{aligned}$$

So that

$$\frac{d^4 u}{d z^4} + \mu^4 u = 0$$

Since

$$e^{i \frac{\mu z}{\sqrt{2}}} = \cos. \frac{\mu z}{\sqrt{2}} + i \sin. \frac{\mu z}{\sqrt{2}}$$

and

$$e^{-i \frac{\mu z}{\sqrt{2}}} = \cos. \frac{\mu z}{\sqrt{2}} - i \sin. \frac{\mu z}{\sqrt{2}}$$

Now, Equation (15) may be written

$$\begin{aligned}u = e^{\frac{\mu z}{\sqrt{2}}} &\left[A^1 \left(\cos. \frac{\mu z}{\sqrt{2}} + i \sin. \frac{\mu z}{\sqrt{2}}\right) + C^1 \left(\cos. \frac{\mu z}{\sqrt{2}} - i \sin. \frac{\mu z}{\sqrt{2}}\right)\right] \\ + e^{-\frac{\mu z}{\sqrt{2}}} &\left[B^1 \left(\cos. \frac{\mu z}{\sqrt{2}} - i \sin. \frac{\mu z}{\sqrt{2}}\right) + D^1 \left(\cos. \frac{\mu z}{\sqrt{2}} + i \sin. \frac{\mu z}{\sqrt{2}}\right)\right] \\ = e^{\frac{\mu z}{\sqrt{2}}} &\left[(A^1 + C^1) \cos. \frac{\mu z}{\sqrt{2}} + i (A^1 - C^1) \sin. \frac{\mu z}{\sqrt{2}}\right] \\ &+ e^{-\frac{\mu z}{\sqrt{2}}} \left[(B^1 + D^1) \cos. \frac{\mu z}{\sqrt{2}} - i (B^1 - D^1) \sin. \frac{\mu z}{\sqrt{2}}\right]\end{aligned}$$

or, using new arbitrary constants

$$u = e^{\frac{\mu z}{\sqrt{2}}} \left[A \cos. \frac{\mu z}{\sqrt{2}} + B \sin. \frac{\mu z}{\sqrt{2}}\right] + e^{-\frac{\mu z}{\sqrt{2}}} \left[C \cos. \frac{\mu z}{\sqrt{2}} + D \sin. \frac{\mu z}{\sqrt{2}}\right]$$

The complete solution of Equation (10) is therefore

$$\left.\begin{aligned}u = \frac{p R^2}{E_0 t} &+ e^{\frac{\mu z}{\sqrt{2}}} \left[A \cos. \frac{\mu z}{\sqrt{2}} + B \sin. \frac{\mu z}{\sqrt{2}}\right] \\ &+ e^{-\frac{\mu z}{\sqrt{2}}} \left[C \cos. \frac{\mu z}{\sqrt{2}} + D \sin. \frac{\mu z}{\sqrt{2}}\right]\end{aligned}\right\} \ldots. (16)$$

From this Equation (16), if $p = w\ (z + h)$, there is obtained

$$\left.\begin{aligned}
\frac{d\,u}{d\,z} &= w\,\frac{R^2}{E_0\,t} \\
&+ \frac{\mu}{\sqrt{2}}\,e^{\frac{\mu z}{\sqrt{2}}}\left[(A+B)\cos.\frac{\mu z}{\sqrt{2}} - (A-B)\sin.\frac{\mu z}{\sqrt{2}}\right] \\
&- \frac{\mu}{\sqrt{2}}\,e^{-\frac{\mu z}{\sqrt{2}}}\left[(C-D)\cos.\frac{\mu z}{\sqrt{2}} + (C+D)\sin.\frac{\mu z}{\sqrt{2}}\right] \\
\frac{d^2 u}{d\,z^2} &= \mu^2\,e^{\frac{\mu z}{\sqrt{2}}}\left[B\cos.\frac{\mu z}{\sqrt{2}} - A\sin.\frac{\mu z}{\sqrt{2}}\right] \\
&- \mu^2\,e^{-\frac{\mu z}{\sqrt{2}}}\left[D\cos.\frac{\mu z}{\sqrt{2}} - C\sin.\frac{\mu z}{\sqrt{2}}\right] \\
\frac{d^3 u}{d\,z^3} &= -\frac{\mu^3}{\sqrt{2}}\,e^{\frac{\mu z}{\sqrt{2}}}\left[(A-B)\cos.\frac{\mu z}{\sqrt{2}} + (A+B)\sin.\frac{\mu z}{\sqrt{2}}\right] \\
&+ \frac{\mu^3}{\sqrt{2}}\,e^{-\frac{\mu z}{\sqrt{2}}}\left[(C+D)\cos.\frac{\mu z}{\sqrt{2}} - (C-D)\sin.\frac{\mu z}{\sqrt{2}}\right] \\
\frac{d^4 u}{d\,z^4} &= -\mu^4\,e^{\frac{\mu z}{\sqrt{2}}}\left[A\cos.\frac{\mu z}{\sqrt{2}} + B\sin.\frac{\mu z}{\sqrt{2}}\right] \\
&- \mu^4\,e^{-\frac{\mu z}{\sqrt{2}}}\left[C\cos.\frac{\mu z}{\sqrt{2}} + D\sin.\frac{\mu z}{\sqrt{2}}\right]
\end{aligned}\right\} \quad (17)$$

Multiplying both sides of Equation (16) by μ^4 and adding to Equation (17)

$$\frac{d^4 u}{d\,z^4} + \mu^4\,u = \mu^4\,\frac{p}{E_0\,t}\,\frac{R^2}{} = \frac{p}{C_1} \quad \ldots\ldots\ldots\ldots\ldots (18)$$

which is Equation (10), thus verifying Equations (16) and (17).

The arbitrary constants A, B, C, and D are determined by the end conditions at the crest and at the base of the dam.

Dam Free to Slide on Base.

As an example, suppose that the base is free to slide on the foundations. Then at the crest $M = F = 0$; that is, by Equations (3) and (4)

$$\frac{d^2 u}{d\,z^2} = \frac{d^3 u}{d\,z^3} = 0$$

and also at the base $M = F = 0$.

From Equations (2), (3), and (17), using the suffix 0 for the crest and suffix 1 for the base, there is found

$$\left(\frac{d^2 u}{d z^2}\right)_0 = \left(\frac{d^3 u}{d z^3}\right)_0 = \left(\frac{d^2 u}{d z^2}\right)_1 = \left(\frac{d^3 u}{d z^3}\right)_1 = 0$$

Now $z = 0$ at the crest and $z = d$ at the base. Hence, putting $z = 0$ in the second and third of Equations (17) and equating to zero,

$$B - D = 0$$
$$-(A - B) + (C + D) = 0$$

and, using the conditions at the base, putting $z = d$ in the same pair of Equations (17)

$$B e^{\frac{\mu d}{\sqrt{2}}} \cos. \frac{\mu d}{\sqrt{2}} - A e^{\frac{\mu d}{\sqrt{2}}} \sin. \frac{\mu d}{\sqrt{2}} - D e^{-\frac{\mu d}{\sqrt{2}}} \cos. \frac{\mu d}{\sqrt{2}}$$
$$+ C e^{-\frac{\mu d}{\sqrt{2}}} \sin. \frac{\mu d}{\sqrt{2}} = 0$$

$$-A e^{\frac{\mu d}{\sqrt{2}}} \left(\cos. \frac{\mu d}{\sqrt{2}} + \sin. \frac{\mu d}{\sqrt{2}}\right) + B e^{\frac{\mu d}{\sqrt{2}}} \left(\cos. \frac{\mu d}{\sqrt{2}} - \sin. \frac{\mu d}{\sqrt{2}}\right)$$
$$+ C e^{-\frac{\mu d}{\sqrt{2}}} \left(\cos. \frac{\mu d}{\sqrt{2}} - \sin. \frac{\mu d}{\sqrt{2}}\right) + D e^{-\frac{\mu d}{\sqrt{2}}} \left(\cos. \frac{\mu d}{\sqrt{2}} + \sin. \frac{\mu d}{\sqrt{2}}\right) = 0$$

Hence

$$A = B = C = D = 0$$

and the solution becomes simply

$$u = \frac{w R^2}{E_0 t} \times z \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (19)$$

hence, by means of Equation (4),

$$T = \frac{E_0 t}{R} \times u = w R z = p R \ldots\ldots\ldots\ldots\ldots (20)$$

which is the ordinary cylinder formula.

The condition which must be satisfied for this formula to be applicable is, therefore, that the dam is free to move, or slide, on its foundations.

Dam with Base Encastrée.

As another example, suppose that the base is fixed and encastrée. then at the base the conditions to be satisfied are

$$u = \frac{d u}{d z} = 0$$

In this case it will simplify the work to take the origin at the base and the axis of Z vertical upward.

The fundamental Equation (10) is then unaltered in form, but the pressure is given by

$$p = w\,(d - z) \qquad (21)$$

The solution, Equation (16), remains the same in form but with p as given in Equation (21) and hence $\frac{d\,p}{d\,z} = -\,w$, so that in the first of Equations (17) the sign of w must be altered from + to —. In order to determine the constants, apply the conditions that

when $z = 0$, $\qquad u = \frac{d\,u}{d\,z} = 0$

when $z = d$, $\qquad M = F = 0$

Therefore, $\qquad \frac{d^2\,u}{d\,z^2} = \frac{d^3\,u}{d\,z^3} = 0$

Hence, from Equation (16) and the first of Equations (17), putting $z = 0$

$$\left.\begin{aligned} \frac{w\,R^2\,d}{E_0\,t} + A + C &= 0 \\ -\frac{w\,r^2}{E_0\,t} + \frac{\mu}{\sqrt{2}}\,[(A + B) - (C - D)] &= 0 \end{aligned}\right\} \qquad (22)$$

For the crest of the dam, putting $z = d$ in the second and third of Equations (17) and equating to zero as before

$$\left.\begin{aligned} -A\,e^{\frac{\mu\,d}{\sqrt{2}}} \sin.\frac{\mu\,d}{\sqrt{2}} + B\,e^{\frac{\mu\,d}{\sqrt{2}}} \cos.\frac{\mu\,d}{\sqrt{2}} + C\,e^{-\frac{\mu\,d}{\sqrt{2}}} \sin.\frac{\mu\,d}{\sqrt{2}} \\ - D\,e^{-\frac{\mu\,d}{\sqrt{2}}} \cos.\frac{\mu\,d}{\sqrt{2}} = 0 \\ -A\,e^{\frac{\mu\,d}{\sqrt{2}}}\left(\cos.\frac{\mu\,d}{\sqrt{2}} + \sin.\frac{\mu\,d}{\sqrt{2}}\right) + B\,e^{\frac{\mu\,d}{\sqrt{2}}}\left(\cos.\frac{\mu\,d}{\sqrt{2}} - \sin.\frac{\mu\,d}{\sqrt{2}}\right) \\ + C\,e^{-\frac{\mu\,d}{\sqrt{2}}}\left(\cos.\frac{\mu\,d}{\sqrt{2}} - \sin.\frac{\mu\,d}{\sqrt{2}}\right) \\ + D\,e^{-\frac{\mu\,d}{\sqrt{2}}}\left(\cos.\frac{\mu\,d}{\sqrt{2}} + \sin.\frac{\mu\,d}{\sqrt{2}}\right) = 0 \end{aligned}\right\} \qquad (23)$$

Since

$$\mu^4 = 12\,\frac{E_0}{E_1} \times \frac{1}{t^2\,R^2}$$

$$\frac{\mu}{\sqrt{2}} = \frac{1}{\sqrt{t\,R}}\left(3\,\frac{E_0}{E_1}\right)^{\frac{1}{4}}$$

Suppose, for simplicity, $E_0 = E_1$; then

$$\frac{\mu}{\sqrt{2}} = \frac{3\frac{1}{4}}{\sqrt{t\,R}} = \frac{1.3}{\sqrt{t\,R}}, \text{ nearly.}$$

In most ordinary cases, $e^{-2\frac{\mu\,d}{\sqrt{2}}}$ can be neglected. Dividing the two Equations (23) by $e^{\frac{\mu\,d}{\sqrt{2}}}$ and neglecting $e^{-2\frac{\mu\,d}{\sqrt{2}}}$, there is found

$$-A \sin.\frac{\mu\,d}{\sqrt{2}} + B \cos.\frac{\mu\,d}{\sqrt{2}} = 0$$

$$-A\left(\cos.\frac{\mu\,d}{\sqrt{2}} + \sin.\frac{\mu\,d}{\sqrt{2}}\right) + B\left(\cos.\frac{\mu\,d}{\sqrt{2}} - \sin.\frac{\mu\,d}{\sqrt{2}}\right) = 0$$

So that

$$A = B = 0$$

Hence, from Equation (22)

$$C = -\frac{w\,R^2\,d}{E_0\,t}$$

$$D = \frac{w\,R^2}{E_0\,t}\left(\frac{\sqrt{2}}{\mu} - d\right)$$

The solution of Equation (16) then becomes, using Equation (21),

$$u = \frac{w\,R^2}{E_0\,t}(d - z) - \frac{w\,R^2}{E_0\,t}\,e^{-\frac{\mu\,z}{\sqrt{2}}}\left[d \cos.\frac{\mu\,z}{\sqrt{2}} + \left(d - \frac{\sqrt{2}}{\mu}\right)\sin.\frac{\mu\,z}{\sqrt{2}}\right]$$

In order to fix the meaning of these equations, consider a cylindrical dam 18 ft. in diameter, 20 ft. deep, and 9 in. thick. In this case, taking $E_0 = E_1$,

$$\frac{\mu}{\sqrt{2}} = \frac{1.3}{\sqrt{\frac{3}{4} \times 9}} = \frac{1.3}{2.6} = \frac{1}{2}$$

very nearly and

$$u = \frac{w\,R^2}{E_0\,t}\left[(d - z) - e^{-\frac{1}{2}z}\left\{d \cos.\frac{1}{2}z + (d - z)\sin.\frac{1}{2}z\right\}\right] \quad (24)$$

the exponential term becomes very small when z is greater than 4 ft. above the base, and this portion of the expression therefore may be neglected, thus reducing to

$$u = \frac{w\,R^2}{E_0\,t}(d - z) \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (25)$$

from which, using Equations (4) and (21)

$$T = p\,R.$$

So that the ordinary cylinder formula becomes applicable within quite a moderate distance of the base, and similarly in any case when $\frac{\mu z}{\sqrt{2}}$ becomes large.

The bending moment at the base is given by Equation (3) and the second of Equations (17). Thus, observing that $z = 0$ and using the values of constants just determined,

$$M = C_1 \frac{d^2 u}{d z^2}$$

$$= \frac{1}{12} E_1 t^3 \times \mu^2 (B - D)$$

$$= -\frac{1}{12} E_1 t^3 \times \mu^2 D$$

$$= -\frac{1}{12} E_1 t^3 \times \mu^2 \times \frac{w R^2}{E_0 t} \left(\frac{\sqrt{2}}{\mu} - d \right)$$

$$= -\frac{w}{\mu^2} \left(\frac{\sqrt{2}}{\mu} - d \right)$$

$$= \frac{w}{\mu^2} \left(d - \frac{\sqrt{2}}{\mu} \right) \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (26)$$

In the case considered above, $\mu^2 = \frac{1}{2}$ and $M = 2\, w\, (d - 2) = 2 \times 62.5 \times 18 = 2\,250$ ft-lb. per foot width.

If instead of a dam in which the water pressure is applied outside, the case of a tank is considered, the sign of p is changed. This case may be dealt with by changing the sign of w, which will then change the arch thrust into a tension and change the sign of the bending moment, and also of course change the sign of u.

Case 2.—Arched Dams of Wedge-Shaped Section.

In treating the case of arched dams with wedge-shaped sections in which the thickness is finite at the crest and increases uniformly with the depth, take the origin at the intersection of the up-stream and down-stream faces and measure z vertically downward. Let

$$t = c\, z \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (27)$$

If l_1 is the distance of the water surface below the origin,

$$p = w\, (z - l_1) \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots (28)$$

where w is the pressure, in pounds per square foot per foot in depth, or the weight of 1 cu. ft. of water, 62.5 lb. Then

$$C_1 = E_1 I = \frac{1}{12} E_1 t^3 = \frac{1}{12} E_1 c^3 z^3 \quad \ldots\ldots (29)$$

Substituting in Equation (7)

$$\frac{1}{12} E_1 c^3 \frac{d^2}{d z^2}\left(z^3 \frac{d^2 u}{d z^2}\right) + \frac{E_0}{R^2} \times c \times z u = p$$

or dividing by $\frac{1}{12} E_1 c^3$

$$\frac{d^2}{d z^2}\left(z^3 \frac{d^2 u}{d z^2}\right) + 12 \cdot \frac{E_0}{E_1} \times \frac{1}{c^2 R^2} \times z u = \frac{12 p}{E_1 c^3} \quad \ldots\ldots (30)$$

Let

$$z = a x \quad \ldots\ldots (31)$$

Substituting in Equation (30) and multiplying by a

$$\frac{d^2}{d x^2}\left(x^3 \frac{d^2 u}{d x^2}\right) + 12 \frac{E_0}{E_1} \times \frac{a^2}{c^2 R^2} \times x u = \frac{12 p a}{E_1 c^3} \quad \ldots\ldots (32)$$

If $l_1 = a l'$, the right-hand side of Equation (32) becomes, using Equation (28)

$$\frac{12 w a^2 (x - l')}{E_1 c^3}$$

Now, suppose that a is chosen so that

$$12 \frac{E_0}{E_1} \times \frac{a^2}{c^2 R^2} = 1 \quad \ldots\ldots (33)$$

Then Equation (32) becomes

$$\frac{d^2}{d x^2}\left(x^3 \frac{d^2 u}{d x^2}\right) + x u = \frac{w R^2}{E_0 c}(x - l') \quad \ldots\ldots (34)$$

which is the fundamental equation on which the solution is based.

A particular integral of Equation (34) is of the form

$$u = A + \frac{B}{x} \quad \ldots\ldots (35)$$

for this gives

$$u x = A x + B$$

and

$$\frac{d u}{d x} = -\frac{B}{x^2}$$

$$\frac{d^2 u}{d x^2} = +\frac{2 B}{x^3}$$

so that

$$x^3 \frac{d\,u}{d\,x^2} = 2\,B$$

$$\frac{d}{d\,x}\left(x^3 \frac{d^2\,u}{d\,x^2}\right) = 0$$

$$\frac{d^2}{d\,x^2}\left(x^3 \frac{d^2\,u}{d\,x^2}\right) = 0$$

Substituting in Equation (34)

$$A\,x + B = \frac{w\,R^2}{E_0\,c}\,(x - l')$$

Hence

$$A = \frac{w\,R^2}{E_0\,c}$$

$$B = -\frac{w\,R^2}{E_0\,c}\,l'$$

so that a particular integral of Equation (34) is

$$u = \frac{w\,R^2}{E_0\,c}\left(1 - \frac{l'}{x}\right) \qquad (36)$$

A general solution (the complementary function) of the equation

$$\frac{d^2}{d\,x^2}\left(x^3 \frac{d^2\,u}{d\,x^2}\right) + x\,u = 0 \qquad (37)$$

may be stated, as follows:

SOLUTION IN SERIES—MICHELL'S FUNCTIONS.

The four solutions of Equation (37) in series form are

$$\left.\begin{aligned}
u_1 &= 1 - \frac{3\,x^2}{(\underline{|3})^2} + \frac{5\,x^4}{(\underline{|5})^2} - \ldots\ldots \\
u_2 &= 4\left[\frac{1\,.\,x}{(\underline{|2})^2} - \frac{2\,.\,x^3}{(\underline{|4})^2} + \frac{3\,.\,x^5}{(\underline{|6})^2} - \ldots\ldots\right] \\
u_3 &= u_1\,(\log.\,x + 2) + \left[1 - \frac{x^2}{(\underline{|3})^2} + \frac{x^4}{(\underline{|5})^2} - \ldots\ldots\right] \\
&\quad - 2\left[1 - \frac{3\,x^2}{(\underline{|3})^2}\,S_3 + \frac{5\,x^4}{(\underline{|5})^2}\,S_5 - \ldots\ldots\right] \\
u_4 &= -\frac{1}{2}\,u_2 \log.\,x + \frac{1}{x} - \frac{x}{(\underline{|2})^2} + \frac{x^3}{(\underline{|4})^2} - \ldots\ldots \\
&\quad + 4\left[\frac{1\,.\,x}{(\underline{|2})^2}\,S_2 - \frac{2\,.\,x^3}{(\underline{|4})^2}\,S_4 + \ldots\ldots\right]
\end{aligned}\right\} \qquad (38)$$

where $$S_n = \frac{1}{1} + \frac{1}{2} + \ldots\ldots\ldots + \frac{1}{n}$$

and $$\underline{n} = 1 \times 2 \times 3 \times \ldots\ldots n$$

This can be verified by differentiation of each series in Equation (38). These will be called Michell's functions.

Solution in Complex Bessel Functions.

A solution of Equation (37) may also be obtained as follows:

Let

$$\left.\begin{aligned} \zeta^4 + (4x)^2 &= 0 \\ \zeta &= \pm \sqrt{2x}\,(1 \pm i) \end{aligned}\right\} \ldots\ldots\ldots\ldots\ldots\ldots (39)$$

Then a solution of Equation (37) is

$$u = \frac{1}{\zeta} J_1(\zeta) \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (40)$$

where J_1 is a Bessel's function of the first order, defined by Bessel's equation

$$\frac{d^2 J_n}{d\zeta^2} + \frac{1}{\zeta} \cdot \frac{d J_n}{d\zeta} + \left(1 - \frac{n^2}{\zeta^2}\right) J_n = 0 \ldots\ldots\ldots\ldots (41)$$

with $n = 1$. This can also be verified by differentiating Equation (40) and using Equations (39) and (41). The four values of ζ give rise to four different solutions of Equation (37).

Connection Between Michell's and Bessel's Functions.

By comparison of the known series for Bessel's functions with the series given above for Michell's functions,

$$\left.\begin{aligned} u_1 &= \frac{1}{\zeta} J_1(\zeta) + \frac{1}{\zeta'} J_1(\zeta') \\ u_2 &= 2i\left[\frac{1}{\zeta}\,(J_1(\zeta) - \frac{1}{\zeta'} J_1(\zeta'))\right] \\ u_3 &= -2(\log. 2 - 1)\,u_1 - \frac{\pi}{4} u_2 + 2\left[\frac{1}{\zeta}\,\Gamma_1(\zeta) + \frac{1}{\zeta'}\,\Gamma_1(\zeta')\right] \\ u_4 &= -\frac{\pi}{2} u_1 + (\log. 2)\,u_2 - 2i\left[\frac{1}{\zeta}\,\Gamma_1(\zeta) - \frac{1}{\zeta'}\,\Gamma_1(\zeta')\right] \end{aligned}\right\} (42)$$

where

$$\zeta = \sqrt{2x}\,(1 + i)$$

$$\zeta' = \sqrt{2x}\,(1 - i)$$

and Y_1* is the usual second solution of Bessel's equation for $n = 1$. Equations (38) and (42) are of course convertible one from the other.

The complete solution of Equation (34) is

$$u = \frac{w R^2}{E_0 c}\left(1 - \frac{l'}{x}\right) + A u_1 + B u_2 + C u_3 + D u_4 \ldots\ldots (43)$$

where A, B, C, D are the four arbitrary constants which are to be determined by the boundary conditions at the crest and at the base, exactly as in Case 1.

Tables of Michell's Functions.

In order to facilitate calculation, tables of Michell's functions have been prepared, giving u_1, u_2, u_3, u_4 and their first three derivatives for all integral values of x from 1 to 30. Attention is drawn to the fact that the values of x are not actual heights, but are merely numbers connected with the height by the relation $z = a x$, where a is given by Equation (33), namely,

$$12 \frac{E_0}{E_1} \times \frac{a^2}{c^2 R^2} = 1$$

For example, if

$$E_1 = E_0$$

$$c = \frac{1}{6}$$

$$R = 150$$

Then

$$a^2 = \left(\frac{1}{6} \times 150\right)^2 \times \frac{1}{12}$$

$$a = \frac{25}{2\sqrt{3}} = 7.2 = \frac{36}{5}, \text{ about,}$$

and the values of x are about $\frac{5}{36}$ of the actual vertical height, so that for a dam of these proportions, 180 ft. high, the value of x is 25.

The tables have been calculated directly from Equation (38). For values of x above 10, this work is troublesome on account of the large number of terms which must be included—and for values of x above 20 the tables cannot be relied on for more than about four

* There is an error in Gray and Matthews' expression for Y_n. The sign of the last term $\left(\Sigma^n \frac{1}{2s}\right)$ should be +, not − as given. The correct expression is given in Jahnke and Emde's Tables.

decimal places. In case it should be desired to use the functions for higher values than those given in the tables, it has been thought advisable to give the semi-converging expressions for Michell's functions, as follows. Let*

$$P_n = 1 - \frac{(4n^2-1^2)(4n^2-3^2)}{\lfloor 2\,(8\zeta)^2} + \frac{(4n^2-1^2)(4n^2-3^2)(4n^2-5^2)(4n^2-7^2)}{\lfloor 4\,(8\zeta)^4} - \ldots.$$

$$Q_n = \frac{4n^2-1^2}{8\zeta} - \frac{(4n^2-1^2)(4n^2-3^2)(4n^2-5^2)}{\lfloor 3\,(8\zeta)^3} + \ldots.$$

and putting $n = 1$, there results

$$P_1 = 1 + \frac{3\times 5}{\lfloor 2\,(8\zeta)^2} - \frac{3\times 5\times 21\times 45}{\lfloor 4\,(8\zeta)^4} + \ldots.$$

$$Q_1 = \frac{3}{8\zeta} - \frac{3\times 5\times 21}{\lfloor 3\,(8\zeta)^3} + \ldots.$$

write

$$\zeta = \sqrt{2x}\,(1+i)$$
$$\zeta' = \sqrt{2x}\,(1-i)$$
$$P_1 = A - iB$$
$$Q_1 = C - iD$$
$$P_1^1 = A + iB$$
$$Q_1^1 = C + iD$$

where

$$A = 1 + 0.009012 \times \frac{1}{x^2}$$

$$B = \quad + 0.029297 \times \frac{1}{x}$$

$$C = \frac{1}{16\sqrt{2x}}\left(3 + 0.20508 \times \frac{1}{x}\right)$$

$$D = \frac{1}{16\sqrt{2x}}\left(3 - 0.20508 \times \frac{1}{x}\right)$$

and call

$$\alpha = \left(\text{sin.}\ \sqrt{2x} - \text{cos.}\ \sqrt{2x}\right)\ \text{cosh.}\ \sqrt{2x}$$
$$\beta = \left(\text{sin.}\ \sqrt{2x} + \text{cos.}\ \sqrt{2x}\right)\ \text{sinh.}\ \sqrt{2x}$$
$$\gamma = \left(\text{sin.}\ \sqrt{2x} + \text{cos.}\ \sqrt{2x}\right)\ \text{cosh.}\ \sqrt{2x}$$
$$\delta = \left(\text{sin.}\ \sqrt{2x} - \text{cos.}\ \sqrt{2x}\right)\ \text{sinh.}\ \sqrt{2x}$$

* Gray and Matthews' "Treatise on Bessel Functions", p. 38 (McMillan and Co., London and New York).

where, as usual, the hyperbolic functions are defined by

$$\cosh.\ \theta = \frac{1}{2}\,(e^{\theta} + e^{-\theta})$$

$$\sinh.\ \theta = \frac{1}{2}\,(e^{\theta} - e^{-\theta})$$

also let

$$H = \sqrt{\sqrt{2}+1} - \sqrt{\sqrt{2}-1} = 0.910181$$

$$K = \sqrt{\sqrt{2}+1} + \sqrt{\sqrt{2}-1} = 2.197365$$

Then the semi-convergent expressions for Michell's functions* are from the expressions for J_n and Υ_n in Gray and Matthews, by substituting $\zeta = \sqrt{2x}\,(1+i)$ and $\zeta' = \sqrt{2x}\,(1-i)$ in

$$J_n(\xi)\sqrt{\frac{2}{\pi\xi}}\left[P_n \cos.\left(\frac{(2n+1)\,\pi}{4} - \xi\right) + Q_n \sin.\left(\frac{(2n+1)\,\pi}{4} - \xi\right)\right]$$

$$\Upsilon_n(\xi) = (\log. 2 - \gamma)\,J_n(\xi) + \sqrt{\frac{\pi}{2\,\xi}}\left[Q_n \cos.\left(\frac{(2n+1)\,\pi}{4} - \xi\right) - P_n \sin.\left(\frac{(2n+1)\,\pi}{4} - \xi\right)\right]$$

where P_n and Q_n have the values given above and γ is Euler's constant 0.577215.....while log. 2 is the Naperian logarithm of 2 or 0.693147 ...., so that $(\log.\ 2 - \gamma) = 0.115931....$

The required expressions are

$$u_1 = \frac{1}{2\sqrt{\pi}\,(2x)^{\frac{3}{4}}}\,[H\,(A\,\alpha + B\,\beta + C\,\gamma - D\,\delta) + K\,(A\,\beta - B\,\alpha - c\,\delta - D\,\gamma)]$$

$$u_2 = \frac{1}{\sqrt{\pi}\,(2\,x)^{\frac{3}{4}}}\,[H\,(-A\,\beta + B\,\alpha + C\,\delta + D\,\gamma) + K\,(A\,\alpha + B\,\beta + C\,\gamma - D\,\delta)]$$

$$u_3 = 2\,(1-\gamma)\,u_1 - \frac{\pi}{4}\,u_2 + \frac{\sqrt{\pi}}{2\,(2\,x)^{\frac{3}{4}}}\,[H\,(-A\,\gamma + B\,\delta + C\,\alpha + D\,\beta) + K\,(A\,\delta + B\,\gamma + C\,\beta - D\,\alpha)]$$

$$u_4 = -\frac{\pi}{2}\,u_1 + \gamma\,u_2 - \frac{\sqrt{\pi}}{2\,(2\,x)^{\frac{3}{4}}}\,[H\,(A\,\delta + B\,\gamma + C\,\beta - D\,\alpha) + K\,(A\,\gamma - B\,\delta - C\,\alpha - D\,\beta)]$$

* Gray and Matthews' "Bessel Functions", p. 40.

Connection Between Solution for Dams for Uniform Thickness and Triangular Sections.

In order to establish the connection between the solution in the case of the wedge-shaped section and the dam of constant thickness, suppose z, and therefore also x, to become indefinitely large and c indefinitely small, so that

$$t = c\,z = c\,(z_0 + z')$$

Where z' is very small, $t = c\,z_0$, approximately constant.

Then, referring to Equations (9), (10), and (33),

$$\mu^4 = \frac{E_0\,t}{C_1 R^2} = 12\,\frac{E_0}{E_1}\cdot\frac{1}{t^2\,R^2} = \frac{c^2}{a^2\,t^2} = \frac{1}{a^2\,z_0^2}$$

$$x = \frac{z}{a} = \frac{1}{a}\,(z_0 + z') = \frac{z_0}{a}\left(1 + \frac{z'}{z_0}\right)$$

hence

$$\sqrt{2\,x} = \sqrt{\frac{2\,z_0}{a}}\left(1 + \frac{z'}{z_0}\right)^{\frac{1}{2}} = \sqrt{\frac{2\,z_0}{a}}\left(1 + \frac{z'}{2\,z_0}\right) = \sqrt{\frac{2\,z_0}{a}} + \frac{z'}{\sqrt{2\,z_0\,a}}$$

$$= \frac{\sqrt{2}}{a\,\mu} + \frac{\mu\,z'}{\sqrt{2}}$$

in which $\dfrac{\sqrt{2}}{a\,\mu}$ is a constant, so that α, β, γ, δ reduce to terms of the form

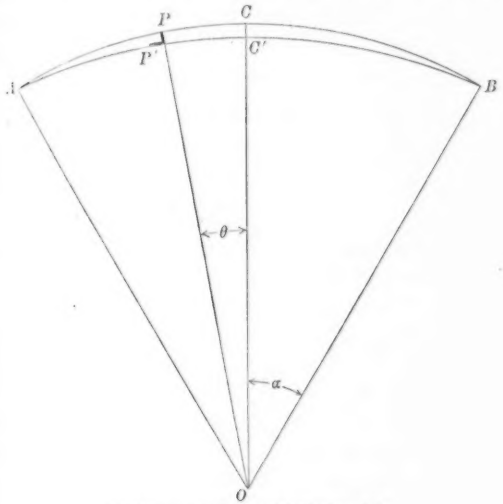
$$\cos\frac{\mu\,z'}{\sqrt{2}}\cdot\cosh.\frac{\mu\,z'}{\sqrt{2}}\ \text{etc.}$$

that is, when x is increased indefinitely and c decreased indefinitely, so as to keep the thickness of the dam constant, Michell's functions reduce to products of circular and hyperbolic functions and the solution degenerates into the form of Equation (16).

APPENDIX II.

DETERMINATION OF THE ELASTIC MODULUS FOR SEGMENTAL DAMS IN TERMS OF YOUNG'S MODULUS E_0 FOR THE MATERIAL USED IN THE DAMS.

Let $A\ C\ B$, Fig. 5, be a segment of a cylinder of unit height and of radius R, subject to a uniform compression S per unit area, free from bending moment and held so that the abutments A and B are fixed in position while the segment can slide freely on its base.



DEFORMATION OF A SEGMENTAL DAM

FIG. 5.

If E_0 is Young's Modulus for the material and f the elastic compression, that is, the ratio of the contraction in length to the original length of any part, then

$$S = E_0 f \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (44)$$

Then, since S is constant throughout, f is constant. If, after deformation, the segment takes up the position $A\ C'\ B$ so that the point P goes to P' and C to C', if

u = the normal displacement toward the axis O

v = the tangential displacement in the direction θ increases, where θ is the angle $P\ O\ C$, C being the middle point of the segment,

then

$$f = \frac{1}{R}\left(-\frac{d\,v}{d\,\theta} + u\right) \quad \ldots\ldots\ldots\ldots\ldots\ldots (45)$$

Now by hypothesis f is constant, hence from Equation (45)

$$-\frac{d\,v}{d\,\theta} + u = f\,R = \text{constant} \quad \ldots\ldots\ldots\ldots\ldots\ldots (46)$$

Assume

$$u = u_0 - u_1 \cos.\,\theta \quad \ldots\ldots\ldots\ldots\ldots\ldots (47)$$

which corresponds to a deformation symmetrical about $O\ C$. From Equations (46) and (47)

$$-v = \int_0^\theta (R\,f - u)\,d\,\theta = \int_0^\theta [(R\,f - u_0) - u_1 \cos.\,\theta]\,d\,\theta$$

$$= (R\,f - u_0)\,\theta - u_1 \sin.\,\theta \quad \ldots\ldots\ldots\ldots\ldots\ldots (48)$$

When $\theta = 0$, $u = C\,C' = U$, say; and when $\theta = \pm\,\alpha$, $u = v = 0$ since A and B are fixed points. Hence, from Equations (47) and (48)

$$\left.\begin{aligned} (R\,f - u_0)\,\alpha - u_1 \sin.\,\alpha &= 0 \\ u_0 + u_1 \cos.\,\alpha &= 0 \\ u_0 + u_1 &= U \end{aligned}\right\} \quad \ldots\ldots\ldots\ldots\ldots\ldots (49)$$

Solving Equation (49) for v

$$U = \frac{R\,f\,\alpha\,(1 - \cos.\,\alpha)}{\sin.\,\alpha - \alpha \cos.\,\alpha} \quad \ldots\ldots\ldots\ldots\ldots\ldots (50)$$

When α is small, approximately

$$\sin.\,\alpha = \alpha - \frac{\alpha^3}{\lfloor 3} = \alpha - \frac{\alpha^3}{6}$$

$$\cos.\,\alpha = 1 - \frac{\alpha^2}{\lfloor 2} = 1 - \frac{\alpha^2}{2}$$

Substituting in Equation (50)

$$U = \frac{R\,f\,\alpha \times \frac{\alpha^2}{2}}{\frac{\alpha^3}{3}} = \frac{3}{2}\,R\,f \quad \ldots\ldots\ldots\ldots\ldots\ldots (51)$$

which is independent of α so long as α is small. When $\alpha = \frac{\pi}{3}$ (so that the angle $A\ O\ B$ is 120°) the coefficient of $R\,f$ is 1.528.... instead of 1.5, so that we may regard Equation (51) as practically true for all ordinary arched dams.

In the given case

$$f = \frac{S}{E_0}$$

from Equation (44), hence,

$$U = \frac{3}{2} \cdot \frac{R}{E_0} S \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (52)$$

Now, if a complete ring of radius R and center O and of Young's Modulus E_0 be subjected to the same stress as above, then

$v = 0$ throughout, and consequently

$$f = \frac{u}{R}$$

Hence,

$$S = E_0 \times f = E_0 \times \frac{u}{R}$$

so that

$$u = \frac{R}{E_0} S \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (53)$$

If S_1, E_0, and R be the same for the segment as for the complete ring, then the displacement of the middle point of the segment is 50% greater than the displacement of any point on the complete ring; that is to say, the displacement of the middle point of the segment is the same as it would be if the segment formed part of a complete cylinder of which the Young's Modulus had a value two-thirds of that which it actually has in the material.

If we suppose the dam divided up into horizontal layers in which S varies from layer to layer, and if we suppose that these layers are free to slide over one another; that is, if we neglect the twist of the surface due to the base being fixed and the displacements not being constant at all points of the arch layers, the displacement of the middle point C will be as given above, and we can obtain the solution for the segmental dam by using the Modulus $\frac{2}{3} E_0$ instead of E_0 in the solution for the complete cylinder.

APPENDIX III.

NUMERICAL EXAMPLE OF CALCULATION OF STRESSES IN A DAM OF TRIANGULAR SECTION.

In the case of the Wooling Dam, the leading dimensions, Fig. 6, are as follows:

Crest width, $A\ C = 2.20$ ft.
Base, $B\ D = 4.40$ ft.
Height, $A\ B = 33$ ft.

So that

$$c = \frac{2.2}{33} = \frac{1}{15}$$

The radius of the arch to the up-stream face is 135 ft. The angle of the sector is about 120° at crest level, so that E_0 is replaced by $\frac{2}{3}\ E$ throughout. The value adopted for E_1 was 2 600 000 lb. per sq. in. and that for E was 2 000 000 lb. per sq. in., the larger value being adopted for the vertical section to make a rough allowance for the vertical reinforcement and the value $\frac{2}{3}\ E$ being used to allow for the segmental form. Then

$$a = c\ R \sqrt{\frac{1}{12} \cdot \frac{E_1}{\frac{2}{3} E}} = \frac{11}{3} \text{ nearly}$$

$O\ A = l_1 = 15 \times 2.2 = 33$ ft.
$O\ B = l_2 = 15 \times 4.4 = 66$ ft.

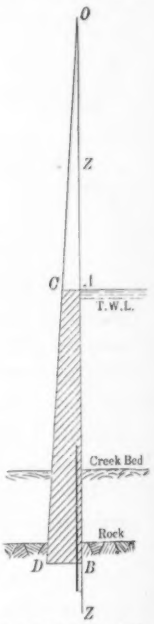
$$x = z \times \frac{1}{a} = \frac{3}{11} \times z$$

Hence, corresponding to A, $x = l_1' = 9$
and corresponding to B, $x = l_2' = 18$

Remembering that, for the segmental dam, $E_0 = \frac{2}{3}\ E$, and calling

$$u = u' \frac{w\ R^2}{E_0\ c} = u' \frac{w\ R^2}{\frac{2}{3} E\ c}$$

$$A = A' \frac{w\ R^2}{E_0\ c}, \text{ etc.}$$



SECTION OF DAM OF TRIANGULAR SECTION, BASE ENCASTRÉE
FIG. 6.

Equation (43) may be written

$$u' = A' u_1 + B' u_2 + C' u_3 + D' u_4 + 1 - \frac{l'}{x} \ldots\ldots (54)$$

From which, by differentiation

$$\frac{d u'}{d x} = A' \frac{d u_1}{d x} + B' \frac{d u_2}{d x} + C' \frac{d u_3}{d x} + D' \frac{d u_4}{d x} + \frac{l'}{x^2} \ldots\ldots (55)$$

$$\frac{d^2 u'}{d x^2} = A' \frac{d^2 u_1}{d x^2} + B' \frac{d^2 u_2}{d x^2} + C' \frac{d^2 u_3}{d x^2} + D' \frac{d^2 u_4}{d x^2} - \frac{2 l'}{x^3} \ldots\ldots (56)$$

$$\frac{d^3 u'}{d x^3} = A' \frac{d^3 u_1}{d x^3} + B' \frac{d^3 u_2}{d x^3} + C' \frac{d^3 u_3}{d x^3} + D' \frac{d^3 u_4}{d x^3} + \frac{6 l'}{x^4} \ldots\ldots (57)$$

CASE 1.—DAM FULL TO CREST LEVEL—NO TEMPERATURE EFFECT—BOTTOM ENCASTRÉE—CREST FREE.

The end conditions for this case are, observing that since the water is at crest level, $l' = l_1'$

at $x = l_1' = 9$

$$M = F = 0 \qquad \frac{d^2 u'}{d x^2} = \frac{d^3 u'}{d x^3} = 0$$

at $x = l_2' = 18$

$$u' = \frac{d u'}{d x} = 0$$

Equations (54) to (57) thus give

at $x = l_1' = 9$

$$A' \frac{d^2 u_1}{d x^2} + B' \frac{d^2 u_2}{d x^2} + C' \frac{d^2 u_3}{d x^2} + D' \frac{d^2 u_4}{d x^2} = \frac{2 l_1'}{x^3}$$

$$= \frac{2 \times 9}{9^3} = + 0.024\,691 \ldots.$$

$$A' \frac{d^3 u_1}{d x^3} + B' \frac{d^3 u_2}{d x^3} + C' \frac{d^3 u_3}{d x^3} + D' \frac{d^3 u_4}{d x^3} = - \frac{6 l_1'}{x^4}$$

$$= - \frac{6 \times 9}{9^4} = - 0.008\,230 \ldots.$$

at $x = l_2' = 18$

$$A' u_1 + B' u_2 + C' u_3 + D' u_4 = - 1 + \frac{l'}{x} = - 1 + \frac{9}{18} = - 0.500\,000 \ldots.$$

$$A' \frac{d u_1}{d x} + B' \frac{d u_2}{d x} + C' \frac{d u_3}{d x} + D' \frac{d u_4}{d x} = - \frac{l'}{x^2}$$

$$= - \frac{9}{18^2} = - 0.027\,777 \ldots.$$

Substituting from the tables and solving according to the tabular form, Table 2:

$$A' = +\,58.583\,319$$
$$B' = +\,15.522\,356$$
$$C' = +\,12.685\,282$$
$$D' = -\,44.117\,258.$$

Observing that

$$M = C_1 \frac{d^2 u}{d z^2} = w\, a^3\, x^3 \frac{d^2 u'}{d x^2}$$

where $a = \frac{11}{3}$ nearly, the bending moments at $x = 9, 10 \ldots\ldots 18$ can be found. Again, observing that by Equation (48)

$$T = \frac{2}{3} E \times \frac{t}{R} \times u = \frac{2}{3} E \times \frac{c\, z}{R} \times u' \times \frac{w\, R^3}{\frac{2}{3} E\, c} = w\, R^2 \times z\, u'$$

the arch thrust at $x = 9, 10 \ldots\ldots 18$ can be found. Diagrams for the thrust and bending moment are given in Figs. 8 and 9.

TABLE 4.—33-Foot Dam, Base Encastrée, Crest Free—Displacements (u), Thrusts (T), and Bending Moments (M).

$u = 0.089\, u'$

$T = w\, a\, R\, x\, u' = 31\,000\, x\, u'$

$M = w\, a^3\, x^3 \frac{d^2 u'}{d x^2} = 3080\, x^3 \frac{d^2 u'}{d x^2}$

$E_0 = \frac{2}{3} E$, where E is Young's Modulus for concrete

d = depth below crest level, in feet

x	z, in feet.	d, in feet.	u, in inches.	T, in pounds per foot height.	M, in foot-pounds per foot width.

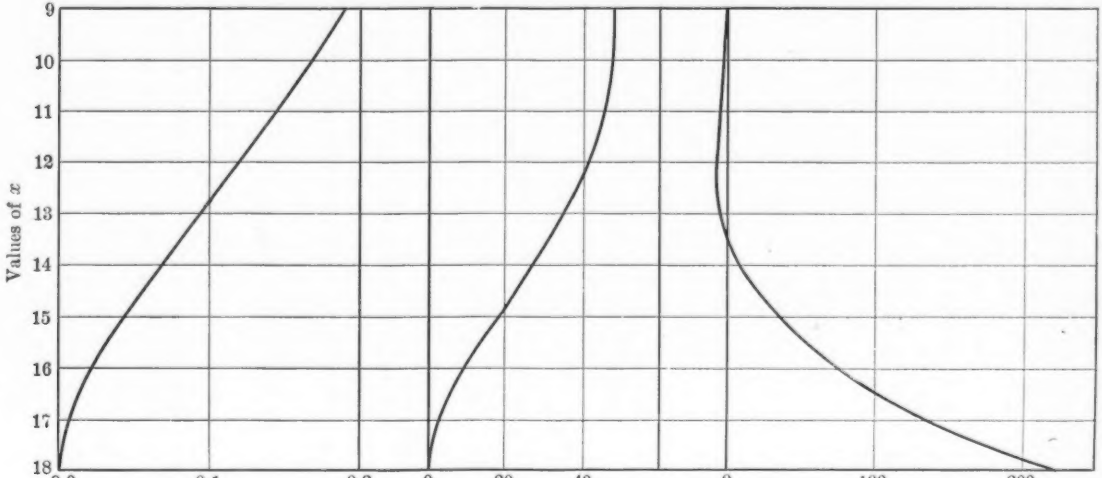

FIG. 7.—DIAGRAM SHOWING DISPLACEMENTS,

FIG. 8.—DIAGRAM SHOWING ARCH THRUST, T

FIG. 9.—DIAGRAM SHOWING BENDING MOMENTS M

FIGS. 7, 8, 9.—DISPLACEMENT, THRUST AND BENDING MOMENT, 33-FOOT DAM, BASE ENCASTRÉE, CREST FREE.

APPENDIX IV.

NUMERICAL EXAMPLE OF CALCULATION OF TEMPERATURE STRESSES, BASE ENCASTREE, CREST FREE.

To deal with this case, suppose the dam empty and proceed as in Section 6, under the heading "Proposed Method of Design, Using Michell's Functions". Put $w = o$ in Equation (43), which then becomes simply

$$u = A\,u_1 + B\,u_2 + C\,u_3 + D\,u_4 \ldots\ldots\ldots\ldots\ldots\ldots (58)$$

Let

θ = the anticipated rise of temperature above the mean temperature during the construction of the dam;

e = the coefficient of expansion of the concrete

The displacement at the center is v toward the axis of the cylinder, where

$$v = e\,R\,\theta \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (59)$$

Equations (54) to (57) are now replaced, when $x = l_1 = 9$, by

$$A\,\frac{d^2 u_1}{d x^2} + B\,\frac{d^2 u_2}{d x^2} + C\,\frac{d^2 u_3}{d x^2} + D\,\frac{d^2 u_4}{d x^2} = 0$$

$$A\,\frac{d^3 u_1}{d x^3} + B\,\frac{d^3 u_2}{d x^3} + C\,\frac{d^3 u_3}{d x^3} + D\,\frac{d^3 u_4}{d x^3} = 0$$

and when $x = l_2 = 18$

$$A\,u_1 + B\,u_2 + C\,u_3 + D\,u_4 = v = e\,R\,\theta$$

$$A\,\frac{d\,u_1}{d\,x} + B\,\frac{d\,u_2}{d\,x} + C\,\frac{d\,u_3}{d\,x} + D\,\frac{d\,u_4}{d\,x} = 0$$

or, calling $A \div e\,R\,\theta = A''$, etc., these become
when $x = l_1 = 9$

$$\left.\begin{aligned} A''\,\frac{d^2 u_1}{d x_2} + B''\,\frac{d^2 u_2}{d x^2} + C''\,\frac{d^2 u_3}{d x^2} + D''\,\frac{d^2 u_4}{d x^2} &= 0 \\ A''\,\frac{d^3 u_1}{d x^3} + B''\,\frac{d^3 u_2}{d x^3} + C''\,\frac{d^3 u_3}{d x^3} + D''\,\frac{d^3 u_4}{d x^3} &= 0 \end{aligned}\right\} \ldots\ldots (60)$$

when $x = l_2 = 18$

$$\left.\begin{aligned} A''\,u_1 + B''\,+ u_2 + C'\,u_3 + D''\,u_4 &= 1 \\ A''\,\frac{d\,u_1}{d\,x} + B''\,\frac{d\,u_2}{d\,x} = C''\,\frac{d\,u_3}{d\,x} + D''\,\frac{d\,u_4}{d\,x} &= 0 \end{aligned}\right\}$$

The coefficients on the left-hand side of Equation (60) are the same as for the case of the dam full, so that the numerical work for the solution is confined to the necessary alteration of the quantities on the right-hand side. Solving,

$$A'' = -\,23.575\,513$$
$$B'' = -\,\;5.099\,821$$
$$C'' = -\,\;7.560\,851$$
$$D'' = +\,19.048\,045$$

Observing that $A = A'' \times e\,R\,\theta$, u is determined, and therefore T and M, throughout for any specified temperature range θ. These must be superposed on the former results.

For the bending moments

$$M = C_1 \frac{d^2 u}{d z^2}$$

but since

$$z = a\,x$$
$$C_1 = \frac{1}{12} E_1 t^3$$
$$t = c\,z$$
$$a^2 = \frac{1}{12} \cdot \frac{E_1}{E_0} \cdot c^2 R^2$$

Therefore,

$$M = \frac{E_0 c^3}{c^2 R^2} z^3 \frac{d^2 u}{d x^2} = \frac{E_0 c a^3}{R^2} x^3 \frac{d^3 u}{d x^2}$$
$$= \frac{E_0 \sqrt{12}\, e\, c\, a^3}{R} x^3 \frac{d^2 u''}{d x^2}$$

where

$$u'' = A''\,u_1 + B''\,u_2 + C''\,u_3 + D''\,u_4$$

In order to find the actual displacements, it is to be observed that the rise of temperature θ was supposed to have caused the dam to expand freely and uniformly throughout, so that the displacement at all points was $v = -\,e\,R\,\theta$. By imagining the dam forcibly brought back so that its base occupies the original position, by making $u'' = 1$ at all points of the base, the corresponding displacements u'' at all points of the dam were found. It is these which must be used for finding the stresses, but to find the displacements, deduct 1 from u'' at all points.

TABLE 5.—(*Continued.*)

$$\frac{d^2 u''}{d x^2} = A'' \frac{d^2 u_1}{d x^2} + B'' \frac{d^2 u_2}{d x^2} + C'' \frac{d^2 u_3}{d x^2} + D'' \frac{d^2 u_4}{d x^2}$$

APPENDIX V.

DEFLECTIONS IN THE WOOLING DAM.

The deflection observations for the Wooling Dam were somewhat rough, as there was considerable oscillation in the plumb line on account of wind. In making the observations, a plumb line was hung from a small triangular notch in an angle iron built into the concrete at crest level, and the distances from the plumb line to the wall were measured at each 5-ft. interval on June 10th, 1916, when the dam was empty, and again on March 28th, 1917, when the dam was nearly full. A comparison of calculated with observed deflections is given in Table 7.

TABLE 7.—COMPARISON OF CALCULATED AND OBSERVED DEFLECTIONS IN THE WOOLING DAM.

Depth below crest.	Displacement, in inches, due to water pressure—dam full —, + when down stream.	Displacement, in inches, due to rise of temperature of 20° Fahr.—dam empty. * Ground level is 23 ft. below crest.

The temperature was not recorded during construction but most of the work was done during the months of March to June, 1916. Table 8 gives the official records of the mean monthly temperature at Macedon, about 3 miles from the dam and at about the same height above sea level. The temperature of the water was observed on November 2d, 1916, to be 13° Cent. = 55° Fahr., and the estimated temperature on March 28th, 1917, was 60° Fahr. The water was then cool, but not cold.

APPENDIX VI.

ACKNOWLEDGMENTS OF ASSISTANCE.

It is desired to acknowledge the assistance given in the investigation by Mr. J. H. Michell (Melbourne) who reduced Equation (30) to the general form, Equation (34), and gave the four series solutions of this equation which have been tabulated as Michell's functions. Acknowledgment must also be made of the assistance given by the writer's assistants Mr. A. French* and Mr. H. M. Sherrard who carried out the laborious work of tabulating Michell's functions and carefully checked every result; also of the courtesy of Dr. Baldwin, the Acting Government Astronomer of Victoria (Australia), for his assistance in suggesting the best method of calculating the tables and for allowing the use of his eight-figure calculating-machine. Finally, mention must be made of the valuable suggestions as to arrangement of subject-matter and as to points requiring further elucidation made by the Publication Committee of the Society.

* Died in active service.

DISCUSSION

Mr. Wernecke.

CHAUNCY WERNECKE,* ASSOC. M. AM. SOC. C. E. (by letter).—The author deserves much credit for working out the needed modification and development of the cylinder theory which has been applied to arched dams. For practical applications, the simple formula for the thickness of an arch dam, $t = \frac{R\ p}{q}$, in which q is the allowable unit stress, does not need revision at the present time, as it has not yet been generally accepted as giving conservative results in dam design. It needs a fuller analysis of its application to dams, which, of course, should be checked by tests and deflection measurements. The author's labors are a worthy addition to this analysis.

That the cylinder theory does give conservative results is shown by Fig. 13 which points out the effect of the radius on the thickness of an arch dam.

It will be seen that the graph of this formula lies on the safe side. A curve giving the thickness of a curved dam having the same factor of safety as the most conservative gravity type would be of the character suggested by the dash line in the diagram. This dash line is merely a suggestion of an approximation to what extended theory and tests may eventually develop. Such a curve, of course, could not be expressed by a single equation, because a change of stress action would occur according to conditions and as the thickness passed certain limits. Where gravity action ceases and arch action begins in the stress action of dams curved in plan, and where arch action ceases and plug or "bracket" action begins in short dams, are problems yet to be solved.

The Arrowrock Dam is curved in plan to a radius of 662 ft., but is of the gravity type. An arch dam with such a radius for a unit stress not exceeding 40 000 lb. per sq. ft. would have a thickness of 103 ft. at a point 100 ft. below the crest. What engineer would not discard the cylinder theory as too conservative should he apply it to the Arrowrock Dam, but, on the other hand, how many engineers would accept its results for the same dam if it was possible to make the radius 300 ft. instead of 662 ft.? Is it not time that all engineers come to realize that it is visually impossible to compare, for relative factors of safety, the profiles or cross-sections of arch dams with those of the gravity type, or with arched dams themselves? The radius is an invisible factor in the cross-section and as important as the thickness itself.

The need for further deflection measurements on existing dams and tests on models is now quite apparent. Unfortunately, the cost

* Seattle, Wash.

of such tests appears to be very great, but the writer believes this is more apparent than real, when considered in the light of the importance of the problem. Mr. Wernecke.

The fact that there are only a few dams compared to the number of such structures as buildings, bridges, or railroad tracks, may account for the slowness with which this subject has been taken up; but the reason of mere lack in numbers is a primitive one, and is offset by the fact that the destruction due to the failure of a dam may be very great. There have been no failures of arch dams to date, but, nevertheless, the factor of safety in these dams must be determined, then their economies will be evident to all.

Adequate tests may not easily be handled by any one institution. In fact, it is a task of co-operation, subsidized by the Government.

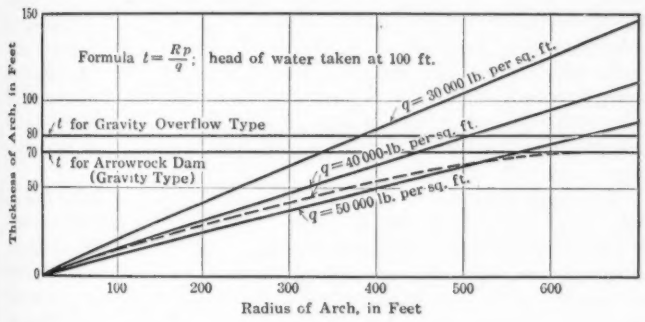

FIG. 13.

Such a testing laboratory would require only a modest sum, as the writer wishes to point out. The cost would depend chiefly on its location and size.

Assuming an easily available site and average size of structure, the cost of a testing plant like that shown in Fig. 14, would be about $250 000. This would include a suitable pump, a portable truck crane, the requisite recording instruments, two traveling bridges, a building, and miscellaneous installations. The operation of the laboratory would be effected as a matter of course. No doubt many of the dams tested would have to be removed from the canyon by blasting.

As a progressive people, Americans have built expensive observatories and telescopes which have assured us that potatoes will grow if planted in the dark of the moon. Why not now build a dam-testing canyon so that engineers will know that better and cheaper dams can be built to aid those very same potatoes in growth and in cooking? In the United States, California has taken the lead in the development

Mr. Wernecke.

of dams and is the home of the arch dam. The climate there is ideal for an outdoor laboratory, economic sites for such a laboratory are numerous, and, furthermore, capable engineers would be found at hand.

That the cost of $250 000 for such a laboratory could be saved in a single dam is easily possible, and this amount is a small part of the outlay on a dam costing from $4 000 000 to $5 000 000. The writer has projected designs of dams for heights from 200 to 450 ft., for which the sites assumed were, in most cases, suitable for an arch or could be built for an arch by using gravity tangent wings. For some of these sites there is a difference in cost of from $500 000 to $1 000 000 in favor of an arch dam as compared to a gravity structure. The final proof that arched dams are safer and better than dams of the gravity type will be of great economic value in the immediate future. The recurring coal strikes, in fact, all labor troubles, development of industries, practicability of electrification of trans-continental railroads, reclamation, and irrigation, are calling for water development more forcefully than ever before, and the ultimate development of every water resource comes in as a guiding limit. This brings up the new problems involved in very high dams—dams which may be even as great as 1 000 ft. in height.

The forerunners of these high dams are already noted. One in India is projected to be 395 ft. high. The Colorado River Dam will be 400 ft. or more in height, and the American Falls Dam, in Idaho, will be a very high one. In view of the fact that comparatively few men are engaged on the construction of dams at any one time, it would seem that no institution other than a Society like this could afford to advance the knowledge on these unprecedented structures, and, accordingly, the Society should proceed actively in this matter. Possibly the best way to present these problems would be apart from any actual structure, which was the method used by the late C. L. Harrison, M. Am. Soc. C. E., in presenting the question of "Provision for Uplift and Ice Pressure in Designing Masonry Dams".*

The use of arch dams is subject to limitations, but at the present time most of these are due to personal opinions. Considering the question of limit of height, Fig. 15 is of interest. This diagram shows the limits in height that result if one holds to the opinions of two early French engineers. M. Delocre (1866), holds that a curved dam would act as an arch if its thickness at the base does not exceed one-third its radius, and M. Pelletreau (1876), believes that this thickness should not exceed one-half its radius.

In a dam, 400 ft. or more in height, the problem as to when arch action ceases is of serious moment. That unprecedentedly high dams

* *Transactions*, Am. Soc. C. E., Vol. LXXV (1912), p. 142.

Showing bridge with set of levers for deflection measurements. The Dam here is 60 ft. long by 50 ft. high. Radius = 100 ft.

FIG. 14.

Mr. Wernecke.

in the immediate future are a certainty, does not need to be argued in this discussion, but engineers with influence in the larger institutions, especially, and others as well, should give substantial encouragement to such analyses as those presented by the author and should see that extended measurements and tests are carried out. It may not be out of place either to call attention to the fact that the water pressure alone at the heel of a 400-ft. dam is 25 000 lb. per sq. ft. and 37 500 lb. per sq. ft. for a 600-ft. structure. This means that the

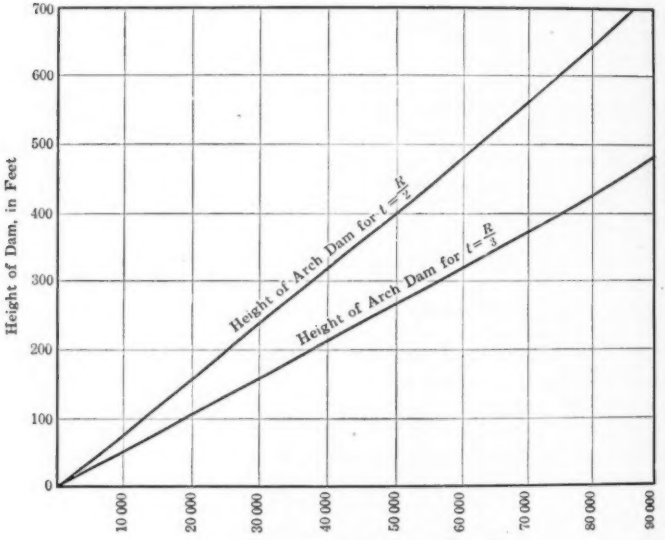

FIG. 15.

present allowed maximum unit stresses must be higher in the future, which means further that tests of unprecedented character must be made.

The author's interpretation of the deflections of the Barren Jack Creek Dam are helpful at this time. Heretofore, too many engineers have referred to these deflection measurements as proof that intricate investigations are of little use. If a concrete arch dam is cast in the coldest weather, subsequent temperatures stresses will cause it to deflect up stream. Does this not warrant writing into construction specifications the requirement of pouring a small vertical central portion, which may be called a key, during the coldest weather

practicable? Between the lines, this seems to have been suggested by the author. Mr. Wernecke.

In conclusion, the writer will state that he has gone into the many intricate, theoretical investigations of determining stresses in arch dams and even projected some himself, but he feels that this phase of the problem has been extended quite beyond practical use; that the burden of support is now on those who can furnish extended deflection measurements, and most of all on the Society, the Government, and on leading technical institutions for adequate tests.

L. R. JORGENSEN,* M. AM. SOC. C. E. (by letter).—The author goes into considerable mathematical detail in his calculations of arch dams. Mr. Jorgensen.

The correct calculation of the various stresses in such dams is only possible when correct assumptions can be made. To make fairly complete calculations of an arch dam is always difficult, but to make correct assumptions is still more difficult. It is not much use to complicate the calculations and expect more accurate results when the assumptions are not correct in the first place.

It is the writer's opinion, based on his experience, that in order to make any assumption hold good for a curved wall in a canyon acting like an arch, it is necessary to fill the contraction joints with grout or concrete during cold weather, with reservoir empty. If that is successfully done, arch action can be expected to be nearly perfect during warm weather, with reservoir full, as hardly any deflection of the crown in a down-stream direction will then take place.

If no deflection takes place, that is, if the decrease in length of the arch due to load should just be compensated for by the increase in length due to the higher temperature (reservoir full, during the warm season), the simple arch formula would hold true, including its modifications in regard to stresses along the up and down-stream faces.

The simple arch formula does not hold true when the arch is thick and flat, and the abutments are closer together; but in such case neither does any other arch formula. The structure becomes a (straight) beam, and the beam action carries the load because much less deformation is required that way.

In such a case, there is only one way to make the curved beam act mainly as an arch, that is, by forcing grout under pressure into the contraction joints. At the bottom, this is difficult or impossible because the contraction joints do not open up close to the bottom on account of the shearing strength of the concrete at the foundation and on account of the action of Poisson's ratio.

The lateral deformation (Poisson's ratio) of the concrete at and near the foundation in high dams is sufficient to give the dam a push in an up-stream direction, so to speak, like a rise in temperature, and

* San Francisco, Cal.

Mr. Jorgensen.

any theory that neglects this factor cannot be considered to be accurate. The lateral deformation of the concrete at the bottom, caused by the weight of material above, should be sufficient to prevent the dam from "lifting off its seat on the up-stream side", due to this tendency of pushing it in an up-stream direction initially.

The beam action will have the same effect, that is, prevent the dam from lifting off its seat, by minimizing the actual deformation in a down-stream direction, with reservoir full.

Any dam calculation which is intended to be complete, must also make provision in some way for the action of the time factor in connection with Young's modulus of elasticity. As long as the stresses in the concrete are kept low, the time factor has no effect, but as soon as the stresses increase toward the breaking point, the effect is such as to change Young's modulus of elasticity, provided, however, that it has taken the stresses at least 14 days to develop fully. This, perhaps, will always be the case for dam structures, as it generally takes much longer than 14 days to fill the reservoir and create the maximum stresses.

It has been fully borne out in practice and by numerous tests, that the deformation of concrete, if highly stressed, is, say, three times greater after a time interval of 14 days or more, than it was just after the load had been applied (Young's modulus). Therefore, it will be found that, in spite of the fact that ordinary formulas may show that a dam structure is or should be cracked or lifted off its seat and it has not done so, the material has stretched more.

What is shown by practice must be taken as being correct, and the ordinary formulas, therefore, are wrong, when it comes to extreme conditions. The concrete will compress or stretch itself much more than in accordance with Young's modulus whenever a time interval is imposed between the occurrence of minimum and maximum stresses, and this is always the case in dam structures.

Mr. Cain.

WILLIAM CAIN,* M. AM. SOC. C. E. (by letter).—The author has made a very valuable contribution to the mathematics of the subject of arched dams. After referring to the ordinary cylinder theory, and noting its inadequacy, he modestly states that:

"This is an attempt to carry the approximation of the cylinder theory a step further by taking account of the shear across a horizontal plane and the corresponding bending moment about a horizontal tangent to the cylinder."

The theory, in its results, is thus closely in line with that to be examined in this discussion, where the effort is made to co-ordinate—at least, approximately—the deformations of the dam acting as a vertical cantilever with its deformations where it acts as a horizontal arch.

* Chapel Hill, N. C.

Mr. Cain.

It is recognized that neither theory is complete, since there is not only shear in a radial direction between the elementary horizontal arches into which the dam is supposed to be divided, but likewise between the arches in an axial direction (perpendicular to the radius), since the shortening of each horizontal arch, when under stress, is different from that of the arch below it, so that each exerts a shearing stress on the next one under it. The second set of axial shearing forces tends to make the dam more rigid than in the case where the horizontal arches are supposed to be free to slide in an axial direction on each other, so that they contribute essentially to the rigidity of a dam, particularly in a V-shaped valley with rigid abutments, hence neglecting them is on the side of safety. It is fortunate that this is so, for to include this second set of shearing forces in an analysis would doubtless make it too complex for solution. In fact, the author's analysis, omitting such forces, is sufficiently complicated as it stands.

The author's analysis, subject to the "reservations" stated in his paper, is complete; in fact, it is more so than any analysis hitherto made, and gives not only the deflections at various depths for points on the dam farthest up stream, but likewise the arch thrusts and moments for temperature changes, as well as for water pressure.

In Appendix II, a short approximate formula is deduced for the radial deflection at the crown of a segmental arch, fixed in position, but free to turn at the ends, on the hypothesis that the arch can slide freely on its base. In reality, each horizontal arch of the dam, to which this formula is applied, is not free at the ends; neither is it "fixed", since the arch is, perhaps, never secured to the sides of the valley in such fashion that the ends can be regarded as encastrée. Further, each arch is not free to slide over the one below it; hence, from both causes, the crown deflection, as given by the formula, is somewhat too large; but, from lack of knowledge as to the true conditions, it may be provisionally accepted, particularly because of its simple form. If thought advisable in the future, the coefficient $\frac{3}{2}$ of this Equation (51) can be changed, to conform to further knowledge, throughout the main mathematical development of Appendix I, which is elegant and rigorous, and leads to the final formulas to be used in practice.

When the dam is reinforced horizontally so that a vertical section of concrete of unit area contains the area, $p_0 \times 1$, of steel, the author properly writes the modulus of elasticity in a horizontal direction, for a homogeneous material, $E_0 = E\ (1 + 15\, p_0)$; for, then, the total stress on the cross-section for the homogeneous material, for a unit

Mr. Cain.

shortening, f, is $E_0 f$, and for the actual section, the stress is $E f$ on the concrete, and $E f \times 15 p_0$ for the steel, or a total of $E f (1 + 15 p_0)$. On equating these two expressions and dividing by f, we are conducted to the formula for E_0 as given. Similarly, the formula for E_1 is derived. The use of these formulas evidently conduces to simplification.

In Appendix I, Michell's functions, with the corresponding numerical values of Table 1, are introduced for the first time. The solution of the arched dams of wedge-shaped cross-section is effected by aid of such functions, as illustrated in the numerical applications to the Wooling Dam, given in Appendices III and IV. The author carefully cautions the reader, in using the tables, to retain six or seven significant figures, on account of the very small resultants found when the functions are properly combined. The writer found the same drawback in computing unit stresses in any direction in the interior of a straight masonry dam,* and was forced to use seven-place logarithmic tables to attain correct results. From what the author says, such a table would have to be used in solving the equations given in Tables 2, 3, and 5, unless a 6 or 8-figure calculating machine is available.

The cylinder formula, $T = p R$, which is utilized in this investigation, is not exact. The strict solution is exactly that derived for thick cylinders, as given (say) in Merriman's "Mechanics of Materials", 10th edition, Articles 149 to 153. Thus, for any horizontal arch of a vertical cylinder, subjected to a water pressure, p per square foot, acting radially and inwards, let,

r = outer radius of cylinder;
r_1 = inner radius of cylinder;
x = distance from center of cylinder to a point in the arch ring;
S = circumferential unit stress, or stress on a radial section which acts perpendicular to the radius.

Then, using Lamé's formula as sufficiently near for the purposes (the other formulas involve Poisson's ratio), we have, since the pressure on the inner surface of the cylinder is zero,

$$S = p\, r^2 \frac{1 + \frac{r_1^2}{x^2}}{r^2 - r_1^2}$$

Thus, S does not vary linearly from $x = r_1$ to $x = r$.

If $t = r - r_1$, the thickness of the arch ring is small compared to r_1, then the unit circumferential thrust at $x = r$ and $x = r_1$ respectively, are, very nearly,

$$S_0 = \frac{p\, r}{t} \quad \text{and} \quad S_1 = \frac{r}{r_1} S_0$$

* *Transactions*, Am. Soc. C. E., Vol. LXIV (1909).

Mr. Cain.

The value of S_0 or the thrust per unit at the outer surface, is the well-known value for a linear arch. Continuing to regard t as very small as compared with r_1, S can be supposed to vary linearly, so that the arch thrust, T, acting on an area, $t \times 1$, is very nearly

$$T = \frac{1}{2} t (S_0 + S_1) = S_0 t \left(\frac{r_c}{r_1}\right) = p r \left(\frac{r_c}{r_1}\right)$$

Where $r_c = \frac{1}{2}(r + r_1)$ is the radius of the center line or axis of the arch.

The usual cylinder formula, $T = p r$, is, thus, not exact, but sufficiently near in most cases. The error is only 1% for the Wooling Dam (Appendix III). The closer approximation might be called for in the case of a thick concrete tank.

The author, in Appendices III to VI, gives the complete numerical solution for the Wooling Dam, which is 33 ft. high, the crest width being 2.2 ft., the bottom width 4.4 ft., and the radius of the up-stream face being 135 ft. The water surface is supposed to be level with the crest, and the dam is supposed to be fixed at the base. The angle of the sector is about 120° at the crest level. In Table 4, for water pressure only, and in Table 6, for a rise of 20° Fahr. in temperature, for reservoir empty, there are given, as the final results of computation for various depths, d, below the crest, the deflection, u (in inches) of the center, the thrust, T, on an arch 1 ft. in height, and the moment, M, per foot width.

Now, consider a cantilever of the dam, enclosed between two radial vertical planes, which make a very small angle with each other. As this angle approaches zero indefinitely, without ever becoming zero, the planes approach parallelism indefinitely and the water pressures on the cantilever all approach parallelism. By the theory of limits, all these pressures can be regarded exactly as if they acted perpendicular to a plane tangent to the upper face of the cantilever along its central vertical generator, which will be taken through a point on the dam farthest up stream. The unit water pressures on this cantilever are precisely the same as for a cantilever contained between two parallel vertical planes, 1 ft. apart, and perpendicular to the tangent plane mentioned to be taken as the water face of the cantilever. For such a cantilever, the unit water pressures become total pressures per foot height and, in what follows, such a cantilever, 1 ft. wide, will be considered.

The dam is supposed to be divided into a series of horizontal arches, each 1 ft. in depth, the mid-plane of each being at a depth, d, as given in Table 4.

In Table 9 are given, for successive depths in feet below the crest, d, the thrust, T, taken from the author's Table 4, the unit water

Mr. Cain. pressure, p, acting on the arch, found by aid of the formula, $T = p\,R$, the unit water pressure, $p' = 62.5\,d$, acting on the dam, and, finally, the pressure on the cantilever, $p' - p$.

In using the formula, $p = \frac{T}{135}$, it is tacitly assumed that each horizontal arch is free to move; in other words, the radial shear acting between adjacent arches is ignored. The author's analysis includes this shear, so that the numerical values for p and $p' - p$, given in Table 9, are only approximate. The interpretation of these figures is as follows:

From $d = 7.3$ to $d = 33.0$, the horizontal load on the cantilever, $p' - p$, is positive and acts down stream, so that both the arches and cantilever are acted on by forces directed down stream at these levels. At $d = 0$, or $d = 3.6$, $p' - p$ is negative, so that the load on the cantilever acts up stream. Thus, at the crest, the cantilever acting alone under the water pressure would deflect more than a horizontal arch of the dam there. This excess deflection is resisted by the arch, thus supplying a force acting up stream on the cantilever. Similarly, at $d = 3.6$, the arch reacts on the cantilever with a force, acting up stream, of 132 lb. per sq. ft. At $d = 5.4$ ft., there is no pressure on the cantilever, the water pressure at that point being carried entirely by the arch.

TABLE 9.

d, in feet.	T, in pounds per foot of height.	$p = \frac{T}{135}$, in pounds per square foot.	$p' = 62.5\,d$, water pressure, in pounds per square foot.	$p' - p$, pressure on cantilever, in pounds per square foot.
0	49 060	363	0	— 363
3.6	48 200	357	225	— 132
7.3	45 800	340	456	+ 116
11.0	41 100	305	687	+ 382
14.6	35 500	263	912	+ 649
18.3	27 600	205	1 144	+ 939
22.0	18 700	139	1 375	+ 1 236
25.6	9 900	73	1 600	+ 1 527
29.3	2 900	21	1 831	+ 1 810
33.0	0	0	2 062	+ 2 062

When the pressure, $p' - p$, on the cantilever is minus, it acts up stream; when $p' - p$ is plus, it acts down stream.

Of course, for the rise of temperature of 20° Fahr., with the reservoir empty, the deflection of an arch is up stream, so that its pressure on the cantilever is everywhere in an up-stream direction. The investigation for the combined water pressure (reservoir full) and a temperature rise of 20° Fahr. (see Tables 4 and 6) is made exactly as the above, and shows similar results, except that the point of no pressure on the cantilever is about 8 ft. below the crest, at which point the arch alone carries all the water pressure.

Mr. Cain.

Recurring now to the case of the reservoir full, but no temperature change, from the unit stresses, $p' - p$, given in Table 9, compute the total loads on successive segments of the cantilever, as shown in Fig. 16.* For greater accuracy in finding the moments, m, about the points, $d = 3.6$, $d = 7.3$, etc., given below, the loads were supposed to be applied at the centers of gravity of the trapezoids or triangles, measuring quantities only to the tenth of a foot.

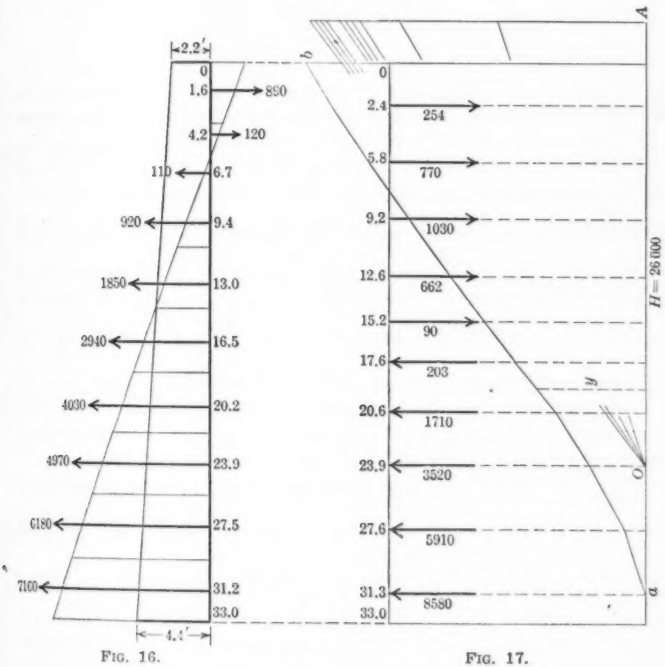

FIG. 16. FIG. 17.

On taking moments of these loads about points at the depths d ft. below the crest, the moments m on the cantilever at the successive depths are derived. The author's moments, M, taken from Table 4, are placed alongside for comparison.

The difference between m and M is given as a percentage of M in the last column of Table 10. It varies from -5.1% to $+8.1\%$, being very small for the three lowest points.

* The line limiting the unit stresses is very nearly straight.

Mr. Cain.

TABLE 10.

d	m	M	Percentage of algebraic increase.
0.0	0	0	.....
3.6	— 1 780	— 1 900	+ 6.3
7.3	— 5 379	— 5 500	+ 2.2
11.0	— 7 237	— 7 500	+ 3.5
14.6	— 4 205	— 4 000	— 5.1
18.3	+ 8 006	+ 7 400	+ 8.1
22.0	+ 33 057	+ 32 600	+ 1.4
25.6	+ 73 330	+ 73 200	+ 0.2
29.3	+ 135 551	+ 134 800	+ 0.6
33.0	+ 222 401	+ 220 900	+ 0.7

The percentage differences being quite small, the inference may be drawn that, ignoring the radial shear between the arches, the moments on the cantilever are only slightly affected. This proving encouraging, the attempt will next be made to compute deflections and compare with the values of u given by the author for the Wooling Dam. The Mohr graphical method will be used*. By this method, the values of $\frac{m}{I}$ should be plotted as horizontal ordinates at the corresponding points of the vertical side of the cantilever. Here, I = moment of inertia of the beam where the thickness is t, so that $I = \frac{1}{12} t^3$. On account of the labor involved in a strict construction, and considering that t does not vary greatly in the vertical segments, Δx, taken not more than 3.7 ft., an average value of t was used for each Δx, so that the moment curve alone was drawn, its area for each base, Δx, computed (designated by $M \Delta x$, where M is an average moment), and the center of gravity of that area found.† Then, omitting for the present the factor, $\frac{1}{12}$, the quantities $\frac{M \Delta x}{t^3}$ were computed and laid off as horizontal forces acting on the cantilever at the corresponding centers of gravity mentioned. The negative forces will act to the right, the positive forces to the left. In Fig. 17, these forces are drawn in position and their magnitudes given. The author gives the value of the modulus $E_1 = 2\,600\,000 \times 144$ lb. per sq. ft.; hence, all lengths being in feet, the deflection at any point, in feet, is given by the formula:

$$\frac{I}{E_1} \sum \frac{M \Delta x}{I} x = \frac{12}{E_1} \sum \frac{M \Delta x}{t^3} x;$$

* Also, see Morley's "Strength of Materials", Articles 82-83.

† Note here that M is the average of m (as computed by the writer and given in Table 10) on the height, Δx. It is not the author's M.

Mr Cain.

therefore, the deflection in inches is:

$$\Delta_x = \frac{12 \times 12}{2\,600\,000 \times 144} \sum \frac{M\ \Delta\ x}{t^3}\ x = \frac{1}{2\,600\,000} \sum \frac{M\ \Delta\ x}{t^3}\ x.$$

In this formula, for any point on the cantilever, x represents the vertical distance from the point to any load, $\frac{M\ \Delta\ x}{t^3}$, below that point, and the summation of the products, $\frac{M\ \Delta\ x}{t^3}\ x$, must include all loads between the point and the base of the cantilever. This summation is easily effected graphically.

Thus, in Fig. 17, assume any pole, O, and lay off, to any convenient scale, vertically, $O\ A = 26\,000$ and from A, to the same scale, lay off horizontally to the left, the loads $\frac{M\ \Delta\ x}{t^3}$, the numerical values of which are 8 580, 5 910, etc., in order; the loads acting to the left being laid off to the left, those acting to the right being laid off to the right. The equilibrium polygon, $a\ b$, is then drawn in the usual manner, and by its known principle, $\sum \frac{M\ \Delta\ x}{t^3}\ x = H\ y$, where y is the ordinate to the equilibrium polygon at the point considered, measured to the scale of distance, in feet. Substituting this value in the preceding equation, we have finally for the deflection in inches at the point where the ordinate, y, is measured,

$$\Delta_x = \frac{y}{100}\ \text{(inches)},$$

where y is measured to the scale of distance, in feet. The values of the deflections thus derived, for the values of d given, are compared with the deflections, u, given by the author in Table 4.

TABLE 11.

d, in feet.	Δ_x, in inches.	u, in inches.	Percentage of excess.
0	0.206	0.188	9.6
3.6	0.182	0.166	9.6
7.3	0.157	0.143	9.8
11.0	0.130	0.118	10.2
14.6	0.102	0.093	9.7
18.3	0.076	0.068	11.8
22.0	0.046	0.042	9.5
25.6	0.023	0.021	10.0
29.3	0.006	0.006	0.0
33.0	0.000	0.000	0.0

The percentage difference is greater than that found in comparing moments. Part of this is due to errors already found in m and part

Mr. Cain. to assuming an average value of t for each segment, Δx, for reasons given previously. To get quite close results, the values of $\frac{M \Delta x}{t^3}$ should be laid off as ordinates, and then using twenty or thirty divisions instead of the ten here adopted, the loads can be computed, etc., and the construction proceeded with as before.

However, the results are again encouraging; for, even if the error amounted to 10%, the approximate method which ignores the shear between the arches is sufficiently exact for a practical solution, considering the many uncertainties in the assumptions concerning curved dams as regards the degree of "fixity" of the base and abutments, the shape of the valley, the proper value for the modulus of elasticity, and, above all, the temperature changes, which cause very high stresses. Then, it will be recalled that the axial shear between the horizontal arches has been ignored in all theories hitherto presented—this fortunately being on the side of safety—so that it seems fair to conclude that a solution that regards the horizontal arches as free to slide on each other should give practical results.

If a simple solution of this character (perhaps partly graphical) co-ordinating perfectly the deflections of arches and cantilevers could be devised, it would prove to be a boon to the practical engineer. For all approximate solutions, the author's paper will prove a valuable standard for comparison, and deserves to become a classic.

Mr. Smith. B. A. Smith,* M. Am. Soc. C. E. (by letter).—In his discussion, Mr. Wernecke has suggested the construction of a large-scale testing laboratory. Would it not be sufficient to construct small-scale models and apply Newton's Principle of Similitude?† It should be remembered that a test to destruction is of no scientific value, for all the elastic equations used are based on Hooke's law—strain varies as stress—and this law breaks down long before the structure fails.

Mr. Jorgensen points out that the correct calculation of the various stresses is only possible when correct assumptions can be made. He might safely have gone a step further and stated, which is quite true, that if complete account is taken of all the actual conditions, a mathematical solution of an engineering problem is impossible.

All that was attempted in the writer's paper was to obtain a solution for the stresses in an ideal case, which is never realized in practice, namely, a complete thin cylinder of uniform material obeying Hooke's law and subjected to water pressure. The approximate solution suggested for the segmental dam is purely tentative. How closely the ideal conditions of this problem are complied with in practice

* Melbourne, Victoria, Australia.

† See Newton's "Principia", Book 2, Section 7, Proposition 32; Routh's "Rigid Dynamics" (1882 Edition), p. 286; also, *Transactions*, Victorian Inst. of Surveyors, Vol. V (1900–09), p. 17.

must be left to the judgment of the engineer who is dealing with the case. Mr. Smith.

In reference to Professor Cain's discussion, the writer would state that it was tacitly assumed, though not expressly stated, that the cylinder is thin, that is, the ratio of the thickness to the radius is small.

The difficulty of determining stresses by graphical methods is very great, a careful scrutiny must be made of the equations on which a graphical method is based in order to insure that fundamental elastic conditions (such, for example, as St. Venant's strain relations) are satisfied, as, otherwise, the results obtained will be quite illusory.

Paper No. 1462

THE DUTY OF WATER IN THE PACIFIC NORTHWEST

By J. C. Stevens, M. Am. Soc. C. E.

With Discussion by Messrs. Thomas H. Means, Robert E. Horton, and J. C. Stevens.

Synopsis

The duty of water for any particular locality is susceptible of analytical determination if the necessary physical characteristics of topography, soil and climate, and the crops to be grown, are known. The object of this paper is to strip this subject of some of the ornate generalities that usually characterize its discussion, and to suggest lines along which future research should be conducted in order to supply the missing data necessary to the solution of the problem.

The subject is first considered analytically. The process is illustrated by an actual example, and the correctness of the determination substantiated by results actually secured on projects where crop statistics and other data are available.

Briefly stated, the determination of the duty of water consists first in fixing the average percentage of soil moisture that should be maintained for the particular soil and crops, and then finding a quantity of irrigation water that, with the precipitation and the unavoidable losses, will maintain that amount of soil moisture.

This method makes the free soil moisture in the root zone of the plants the index of plant sufficiency. It is hoped that the suggestion will lead to additional research to determine the amount of free soil moisture

in various types of soils and for various crops, that will give the highest efficiency in agricultural practice. Some work along this line has already been done and the results of such investigations have been used in making up the various formulas and criteria presented in this paper.

Terms Used.

The net duty of water is taken to mean the quantity of water artificially delivered to the margin of the farms for irrigation. It will be expressed in depth on the land in feet or inches, which is identical with acre-feet or acre-inches per acre.

Precipitation includes rain, snow, hail, sleet, dew, and frost.

Irrigation water is the water artificially delivered to the land. It does not include precipitation.

Evaporation is the return of surface water to the atmosphere. It is considered in three phases—evaporation of precipitation, of irrigation water, and from soil storage.

Percolation is the passing of water in the soil beyond the reach of plant roots.

Surface waste is the surface run-off from irrigation water or precipitation.

Soil storage is the water held in the soil by capillary forces within the root zone of plants.

Water-table is the point of soil saturation by gravity water.

Hygroscopic moisture is the quantity of water an artificially heated soil will absorb from moist air upon cooling. It is not available for plant growth.

Capillary water is the water held in the interstices of the soil against gravity.

Gravity water is all water in the soil not hygroscopic or capillary. It will flow off by gravity in drains.

Plant consumption is the water taken by plant roots.

Free moisture is any soil water available for plant growth.

What Constitutes the Net Duty of Water.

The net duty of water is very simply conceived in two parts:

1.—The quantity of water actually consumed by plants; and,

2.—The losses incident to supplying that quantity to the plant roots.

The losses are of three kinds:

1.—Evaporation,

2.—Percolation,

3.—Surface waste.

Of these losses, percolation and surface waste are entirely under the control of the irrigator, while evaporation is partly under control. It is only necessary, therefore, to consider to what extent these losses, in the exercise of good husbandry, are necessary and unavoidable and thus may be considered a beneficial use of water.

Plant Consumption.—Every plant requires certain ideal conditions for optimum growth. These conditions involve a minimum water consumption. Any material departure from these ideal conditions is reflected in an increased water consumption. In other words, Nature tries to remedy any deficit of plant food, or energy, by an increase in transpiration.

It has been found that the water consumption of plants is influenced by environmental factors as follows:

1.—The addition of fertilizer to a fertile soil has no effect on plant consumption, but materially reduces the water consumption if added to an infertile soil.

2.—Soil moisture is without effect provided there is sufficient for plant growth.

3.—Radiation, *i e.*, intensity of sunlight, increases transpiration in almost direct proportion.

4.—Transpiration varies almost directly with the saturation deficit (*i. e.*, 1 — relative humidity).

5.—Cool-weather plants, such as wheat, barley, rye, oats, etc., use a minimum of water in cool weather and a maximum in warm weather.

6.—Warm-weather plants, such as corn, millet, rice, sorghums, etc., use a minimum of water in warm weather and a maximum in cool weather.

7.—Wind movement increases plant consumption.

8.—A lack of carbon dioxide, the presence of parasites, frequent cropping or any other deleterious influence will increase the water consumption.

By far the most extensive experiments on the water consumption of plants are those of Messrs. Briggs and Shantz* at Akron, Colo., 1911-15.

The method followed was to grow plants in suitable pots, with their surfaces sealed by wax. A record of the quantity of water supplied during growth was kept. At maturity the plants were removed and kiln-dried. The consumption is expressed in pounds of water per pound of dry matter or grain produced. Table 1 gives a summary of the results thus secured.

TABLE 1.—Plant Consumption in Pounds of Water per Pound of Kiln-Dried Matter and of Grain Obtained at Akron, Colo., 1911-12-13.

	Crop (Mean of Genus).	Pounds of Water per Pound of	
		Grain.	Whole plant.
Grains	Proso	454	293
	Millet	483	310
	Sorghum	767	322
	Corn	1 250	368
	Wheat	1 350	513
	Barley	1 400	534
	Oats	1 600	597
	Rye	2 000	685
Hay	Sweet Clover	.....	770
	Vetch	.....	794
	Red and Crimson Clover	.....	797
	Alfalfa, four varieties	.....	831
	Wheat and Brome Grass	.....	861
Tubers	Sugar Beets	.....	397
	Potatoes	.....	636
Weeds	Tumble Weed	.....	287
	Purslane	.....	292
	Buffalo Grass	.....	308
	Russian Thistle	.....	336
	Mountain Sage	.....	616
	Sunflower	.....	683
	Western Ragweed	.....	948

In applying the results obtained at Akron to any particular locality, a comparison of climatic conditions will indicate whether or not additions or reductions should be made. For forage crops, the consumption ratio must be reduced to terms of cured hay, instead of dry matter. Ordinarily, about 70% of the consumption for dry matter can be used with safety.

Making this reduction, for alfalfa and clover the water consumption is 0.42 ft. in depth per ton of cured hay produced. For the grains, wheat

*Journal of Agricultural Research, Vol. 3, No. 1, and Bulletin 235, Bureau of Plant Industry, U. S. Department of Agriculture.

will require 0.03 ft.; oats, 0.02 ft.; rye, 0.04 ft.; and barley and corn, 0.025 ft. in depth per bushel of yield.

With these data, it is possible to determine for any particular locality, crop classification and yields, the approximate quantity of water that will be required for plant growth.

The monthly rate at which water is consumed may be taken as approximately proportional to the monthly increment to temperature during the period of growth. Thus, assuming that growth begins April 1st, the total plant consumption may be distributed in proportion to the increase of monthly temperature over that of March.

Evaporation.—Having determined the quantity of water consumed in plant growth, it is necessary to determine the losses incident to supplying that quantity to the plants. The three sources of loss, *viz.*, evaporation, percolation, and surface waste, will be considered in order.

As previously stated, evaporation is under the partial control of the irrigator. A great saving can be made by irrigating in deep furrows, by cultivation and maintaining a mulch on the surface. For alfalfa hay, the water should be applied just before cutting in order to start the second crop. The old plants shade the ground and diminish the effect of wind, thus greatly reducing evaporation.

Evaporation is considered in three phases according to the origin of the water evaporated:

1.—From precipitation.
2.—From irrigation water at the time of application.
3.—From soil storage, *i. e.*, water raised by capillary action to the surface and then evaporated.

The amount of precipitation evaporated can only be fixed arbitrarily. Light summer showers may all be lost, and of heavier rains from 20 to 75% is likely to be dissipated. In duty-of-water calculations it is only practicable to consider the normal monthly precipitation. The following formula will give approximate results for temperatures above freezing:

$$E_r = \frac{T}{100}\sqrt{R} \qquad (1)$$

Where E_r = Evaporation from precipitation, in inches per month;
T = Mean monthly temperature, in degrees Fahrenheit;
R = Monthly precipitation, in inches.

The quantity of irrigation water evaporated immediately following its application will depend on the condition of the soil, nature of crops, and method of its application. When water is first applied the rate of evaporation is high, but the quantity available for evaporation rapidly diminishes as the water soaks into the soil. Once in the soil, it can only be evaporated by being raised to the surface by capillarity when the surface becomes dryer than the soil below. Experiments show that 10% of the quantity applied is a conservative figure for gently rolling or level lands. For steeper lands, from 15 to 25% may be allowed. Losses in excess of these quantities are readily prevented and cannot be considered a beneficial use of water.

Evaporation from soil storage constitutes the most important source of loss. It has been found that there is a fairly definite relation between the amount of evaporation, the moisture content, and temperature of the top soil layer. This relation is practically independent of the nature of the soil.

When the water-table is within the zone of capillary rise, there is a certain moisture content in the top layer which depends on the height of capillary rise for that particular soil, and the position of the water-table. For a soil of uniform texture, the free moisture content may, for practical purposes, be considered to vary uniformly from saturation at the water-table to zero at the limit of capillary rise. For example, consider a soil with 40% voids and of such fineness that the limit of capillary rise is 5 ft. If the water-table is 5 ft. below the surface, the free moisture content at the surface will be zero and there will be no evaporation. If the water-table should rise to 4 ft., the free moisture content of the top layer becomes one-fifth that at saturation, or 8% by volume, and evaporation soon begins.

The soil properties required for the determination of evaporation are the percentage of voids and the limit of capillary rise. The latter will vary somewhat with temperature, but will be found to have values varying from a few inches in coarse sands to 10 ft. or more in fine silts and clays. It can be determined by packing soils in long glass tubes closed at the bottom with muslin. The bottoms are then set in a shallow tank of water and the height to which the water rises is observed. It may require several months to determine this limit in the finer soils.

The results secured by Charles H. Lee,* M. Am. Soc. C. E., in Owens Valley, California, constitute the only data on soil evaporation extending over an entire year. His results also include the transpiration of salt grass. The loss was measured from buried tanks in which the water-table was maintained at various levels. In Table 2 is given a summary of his results.

In the absence of more complete information, the following formula for soil evaporation is presented. The only claim for it is that it approximately fits the results of Lee's experiments in Owens Valley.

$$E_g = 0.18 \left(1 - \frac{d}{H}\right)(T - 32)\, K \quad \ldots\ldots\ldots\ldots (2)$$

in which

E_g = Evaporation from soil, in inches per month;
d = Depth to the water-table;
H = Height of capillary rise;
T = Mean monthly temperature;
K = Factor having a value of unity for the Owens Valley experiments.

* *Water Supply Paper No. 294*, U. S. Geological Survey.

The results obtained by R. B. Sleight,* Jun. Am. Soc. C. E., at the Denver laboratories, indicate that this formula would be approximately applicable to them if the results covered an entire year. Individual months are likely to be in error where air temperatures are used, but in the entire year such errors are compensating.

The following shows the agreement between the evaporation by the formula and that measured in Owens Valley for the year from June, 1910, to May, 1911, inclusive:

Tank No.	Observed.	By Formula.	Percentage of Error.
1	39.9	46.1	+ 14
2	8.0	17.3	+ 116
3	22.5	20.3	— 10
4	23.3	25.0	+ 7
5	30.5	31.9	+ 4
6	42.6	40.3	— 5
7	43.2	45.8	+ 6

The soil in Tanks Nos. 1 and 2 was stratified sand and clay. In the other tanks the soil was of uniform texture, a "mixture of clay, soil and fine sand". Tank No. 1 was covered with 30 in. of clean river sand and the water-table was always in this sand, while the others were covered with the original salt-grass sod. This explains the error of the formula as applied to Tanks Nos. 1 and 2.

Where ground-water is not in evidence, the formula may be written:

$$E_g = \frac{0.18}{V} M (T - 32) K \quad \ldots\ldots\ldots\ldots\ldots\ldots (3)$$

in which,

V = Percentage of voids in the soil;

M = Free moisture content of the soil, in percentage by volume.

If the soil is shaded by crops or is covered with a mulch or well cultivated, a substantial reduction must be made. This is provided for by the factor K which has decreasing values as the crop growth advances. Since crop growth is largely influenced by temperature, the factor K may be expressed in terms of mean monthly temperature. The

* "Evaporation from the Surfaces of Water and River-bed Materials", *Journal of Agricultural Research*, July 30th, 1917.

following is suggested for the case of diversified farm crops well cultivated:

$$K = 1 - \frac{1}{80}(T - 32) \quad \ldots\ldots (4)$$

Percolation.—Percolation is from two sources: (1) irrigation water, and (2) precipitation.

It has been thoroughly demonstrated in practice that the quantity of irrigation water lost by percolation is entirely under the control of the irrigator, provided his supply is sufficiently elastic to permit him to adopt the proper methods of application.

In the arid regions enough percolation from both sources must occur to overbalance the evaporation from soil storage. If this takes place, there can be no accumulation of alkali in the upper soil layers. Any percolation in excess of that required to prevent alkali accumulations cannot be considered a beneficial use of water.

The amount of percolation from precipitation is governed by three factors:

1.—Topography.
2.—Character of soil and crops.
3.—Amount and character of precipitation.

In the arid regions there is comparatively little loss from this source. During snowfall, percolation is deferred until snow melting occurs and the frost is out of the ground.

The following formula may be used to give approximate results for monthly values of precipitation of more than 1 in.; for values less than 1 in., it may safely be assumed that there will be no loss:

$$P_r = \frac{1}{10}(R - 1)\,N \quad \ldots\ldots (5)$$

in which,

P_r = percolation from precipitation, in inches per month;
R = monthly precipitation, in inches.

N is a factor having the following values:

For level or gently rolling lands of sandy loam	1.0
For steeper slopes of clay soils	0.7
For very sandy or gravelly lands	1.5

Percolation from both precipitation and irrigation water continues throughout the year, as evidenced by measured outflow from drains. The calculations for duty of water are greatly simplified if percolation is assumed to occur simultaneously with the evaporation losses from soil storage. After the total amount for the year has thus been determined, it may be redistributed in accordance with the following average percentages of the total:

Month.	Percentage.	Month.	Percentage.
January	4	July	13
February	4	August	13
March	6	September	12
April	7	October	8
May	10	November	6
June	12	December	5
		The year	100

Surface Waste.—This loss is also from the same two sources—irrigation water and precipitation. That from irrigation water is entirely under the control of the irrigator, and although it is possible to eliminate all loss from this source it is not practicable to do so.

Surface waste from nearly a thousand separate tracts was measured in Idaho by Mr. Don H. Bark* during his "Duty of Water Studies" for that State. As a result of these investigations, Mr. Bark states that "under Idaho conditions, from 7½ to 12½% of the amount applied should be allowed in water right contracts" for surface waste. On level or gently rolling land, about 10% may be taken as a liberal figure. On steeper lands an allowance of 15% of the amount applied may be justified. On sandy or gravelly soils, these figures should be halved, and on clay soils they should be increased one-third.

The surface waste from precipitation is generally called run-off, and is governed by the same factors as percolation from precipitation, but in different degrees. As a guide the following formula may be used:

$$S_r = \frac{3}{10}(R - 0.5)\,F \qquad (6)$$

Where S_r = Surface waste from precipitation, in inches per month;
R = Monthly precipitation, in inches.

* Reports, State Engineer of Idaho, 1911–14.

F is a factor having the following values:

For steeper clay soils	1.5
For gently rolling loams	1.0
For rolling sandy soils	0.5
For level sandy soils	0.2

The monthly distribution of surface waste is concurrent with the supply.

Calculation of the Net Duty of Water.

In determining the duty of water for any particular set of conditions it is necessary to consider the entire year, not the irrigation season alone. Two fundamental criteria will be advanced by which the correctness of any such determination may be judged. They are:

1.—The total quantity of water received during the mean year must be such as neither to increase nor deplete the soil storage beyond a predetermined quantity that is most advantageous to plant growth.

2.—The total amount of percolation must overbalance the evaporation originating from soil storage.

In applying the first criterion, it is necessary to determine the limits between which the soil storage may be allowed to fluctuate without harm to the plants. Then fix the quantity of irrigation water to be applied such that, after adding thereto the mean precipitation and deducting therefrom the plant consumption and necessary losses, the quantity of water in soil storage remains between these limits and at the end of the year has the same value as at the beginning.

The optimum free moisture content for healthy farm crops is known to be such that the soil voids are from 40 to 60% filled with water, leaving the remaining space for air.

The minimum free moisture content is a quantity that will just maintain plant growth without wilting. The wilting point was found from more than 1 300 determinations,* to be such that the free moisture was one-half the hygroscopic moisture. The minimum free moisture content therefore may be safely taken as double that at which wilting occurs, or just equal to the hygroscopic moisture.

For diversified farm crops, it is only necessary to consider a depth of soil equal to the root zone of plants, and experience in farm drainage

* "Water Requirements of Plants", *Bulletin 285*, Bureau of Plant Industry, U. S. Department of Agriculture, 1913.

TABLE 3.—Optimum and Minimum Free Moisture in 5 Feet of Typical Soils, Expressed as Depth in Inches on the Land.

Soil.	Percentage of voids.	Optimum free moisture content.	Minimum free moisture content.
Coarse sand	36	13.0	0.5
Fine sand	38	13.7	1.8
Sandy loam	40	14.4	3.9
Fine sandy loam	45	16.2	5.3
Loam	48	17.3	6.8
Clay loam	50	18.0	8.2
Clay	52	18.7	8.5

has proven that 5 ft. should be kept free of ground-water. Therefore, computations may be safely based on the upper 5 ft. of soil.

What an optimum soil moisture of 60% of voids filled with water, and a minimum soil moisture of double that of the wilting point, mean, in inches of depths over 5 ft. of soil, are given in Table 3. The last two columns show the upper and lower limits between which the soil storage should be maintained.

Some of the coarser soils will not hold the optimum moisture content by capillarity. Hence, it is a decided waste of water to try to maintain a moisture content greater than the capillary capacity of the soil in question.

The second criterion is based on the fact that in humid regions where the percolation exceeds soil evaporation, there are no surface accumulations of alkali. On the other hand, such accumulations are always in evidence wherever the upward movement of water in the soil is not overbalanced by the downward movement.

With these two criteria as guides, it is possible to determine the quantity of water required to maintain any desired degree of soil moisture, which, in effect, constitutes the net duty of water. This quantity is that required to balance the receipts and disbursements of water on the land during the mean year.

The physical factors that must be known in advance are:

1.—Soil characteristics as to porosity, height of capillary rise, capillary capacity, depth and uniformity of texture.

2.—Topography.

3.—Mean monthly and mean annual temperature.

4.—Mean monthly and mean annual precipitation.

5.—Probable crops and yields.

In making the calculations we may first arrive at approximate values by using the mean annual climatic factors.

Let R = Mean annual precipitation;
I = Irrigation water to be applied (net duty);
C = Total annual plant consumption;
P_i and P_r = Total annual percolation loss from irrigation water and from precipitation, respectively;
S_i and S_r = Total annual surface waste from irrigation water and from precipitation, respectively;
E_i, E_r, E_g = Evaporation from irrigation water, precipitation, and soil storage, respectively.

Balancing the total water receipts and disbursements on the land, we may write:

$$I + R = C + (P_i + P_r) + (S_i + S_r) + (E_i + E_r + E_g) \ldots . (7)$$

In this expression, R and C are known, independent quantities, E_r, P_r, and S_r, may be found in terms of R; also E_i and S_i may be expressed in terms of I. From the second criterion, we also have:

$$P_r + P_i > E_g \ldots \ldots \ldots \ldots \ldots \ldots \ldots (8)$$

But as E_g is itself a function of both I and R and the monthly temperatures, a tentative solution only is possible.

It will be found that the net duty, I, will be given in terms of either average soil moisture content or of the position of the water-table, which in turn is an index of the soil moisture above it.

Hence, if we can determine the most advantageous soil moisture content for the particular case in hand, we may fix I, the net duty of water.

Calculated Duty for the Boise Project, United States Reclamation Service.

The application of the foregoing principles will be illustrated by a concrete example. The Boise Project in Idaho will be used, since the duty of water there has been fairly well determined.

Plant Consumption.—The crop statistical reports of the United States Reclamation Service were averaged for the years 1914-1917, inclusive. The acreage used is that of 1917. The plant consumptions as determined at Akron, Colo., were applied without reduction for climatic differences.

As shown in Table 4, a mean plant consumption of 1.06 ft. or 12.7 in. per year was indicated. In distributing this amount it is assumed that growth begins on April 1st, and that the distribution is proportional to the increase of mean monthly temperature over that of March, as in Table 5.

Precipitation.—The losses from precipitation and the net amount going to soil storage are next found from Formulas (1), (3), and (4), as in Table 6.

Soil Evaporation.—This is found from Formulas (3) and (4). The soil is assumed to average 5 ft. in depth and to be of level or gently rolling sandy loam. An average soil porosity of 40% was used. The water-table was assumed to be either naturally, or kept by drainage, below the 5-ft. level.

The monthly expressions for evaporation from soil storage are thus found as in Table 7.

The last column shows the multipliers of the average monthly free soil moisture content, M, to obtain the soil evaporation for that month.

TABLE 6.—TOTAL LOSS AND AMOUNT OF SOIL STORAGE.

Month.	R	T	E_r	P_r	S_r	Total lost.	To soil storage.

December	0.2	1.00	0.0
The year	17.6	0.76	5.36 M

In order definitely to fix the quantity of irrigation water to be applied, first fix the desired average quantity of soil moisture to be maintained. The distribution of moisture in the soil is anything but uniform, and there is always a movement of moisture from the wet to the dry soil by capillary action. It is only practicable, however, to consider the average monthly free moisture content in these calculations.

Now substitute in Equation (7) the values already determined, and, since P_r is small, place $P_i = E_g$, also E_i and S_i each equal 0.1 I, to obtain the net duty in terms of average soil moisture:

$$I = 2.5\ E_g + 9.5 \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (9)$$

Now substitute for E_g twelve times its mean annual value and

$$I = 160\ M + 9.5 \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (10)$$

From Equation (10) it is evident that to maintain an average soil moisture of 10%, or $M = 0.1$, requires 25.5 in. of irrigation water; 12½% requires 29.5 in., and 15% requires 33.5 in. These, however, are only tentative values for selecting a trial value of I.

TABLE 8.—Monthly Distribution.

Month.	Percentage of total.	I.
April	4	1.2
May	12	3.6
June	18	5.4
July	23	6.9
August	24	7.2
September	13	3.9
October	6	1.8
	100	30.0

The proper average soil moisture for the standard farm crops is a fruitful line of research on which there are few or no actual data. It is believed for the case in hand that an average soil moisture of 12 to 14% should be maintained, hence a trial value of $I = 30$ in. will be taken with the monthly distribution indicated in Table 8.

Now deduct the plant consumption and all determined losses from the sum of R and I; the remainder is the amount lost by soil evaporation and percolation of irrigation water. In the first calculation, P_i and E_g are assumed to be concurrent losses. A probable value for soil moisture for April is assumed as desirable at the beginning of the irrigation season. This percentage of soil moisture is applied to the multiplier for E_g (Table 7) in order to obtain the value of E_g for the succeeding month. Double this quantity (2 E_g) is then deducted from the remainder avail-

able for P_i and E_g, to obtain the increment or decrement to soil storage which, in turn, gives the soil moisture increment or decrement from which the average soil moisture for the next month is obtained. In this manner, by repeated trials, a value of soil moisture at the beginning of the season is found such that the total soil evaporation E_g is equal to half the remainder available.

The monthly values of soil moisture must remain within the prescribed limits of optimum and minimum values heretofore established and the algebraic sum of the increments thereto must be zero. If this

cannot be obtained with the assumed value, a new value of I is tried until a value is found that will balance the receipts and disbursements of the soil, maintain the soil storage between the prescribed limits, and neither increase nor deplete the total soil storage during the year. After this is found the percolation loss is redistributed by months in accordance with the schedule of monthly percentages previously given, and the necessary adjustments in soil moisture are made.

Table 9 shows the balance sheet for the Boise Project so obtained; and in Fig. 1 the principal data are shown graphically.

Summarizing the various quantities, Table 10 is obtained.

TABLE 10.—SUMMARY.

	Depth, in inches.		Percentage of total.
RECEIPTS:			
Irrigation water	30.0	....	....
Precipitation	12.8	42.8	100
DISBURSEMENTS:			
Plant consumption	12.7	....	30
Evaporation.....E_g 8.15			
E_r 5.2			
E_i 3.0	16.35	....	38
Percolation.....P_r 0.4			
P_i 8.15	8.55	...	20
Surface waste.....S_r 2.2			
S_i 3.0	5.2	....	12
Total	....	42.8	....
Total losses	30.1	....	70

Note that the total percolation loss of 8.55 in. overbalances the soil evaporation loss of 8.15 in. by 5%, and that all the other criteria outlined are complied with.

In order to judge of the consistency of these figures, a study was made of the actual use of water and crop statistics of three projects of the United States Reclamation Service for the four years 1914-17, inclusive, with the results given in Table 11.

On the Klamath Project only 48% of the total water received was lost. The soil on this project is such that the danger of waterlogging the land has led the irrigators to use a comparatively small quantity of water, about 1.0 ft. being artificially applied.

On the Boise Project the average water received was 42.5 in., of which 72% was lost. In the previous analysis, a total receipt of 42.8 in. was determined as necessary, of which 70% is lost. Of this amount 12.8 in. is precipitation and 30 in. is irrigation water. The agreement between the theoretical requirements and the average used during the four years is striking.

Mr. Bark's conclusions are that: "The duty for projects planted to diversified crops on the average clay loam soils of South Idaho should be sufficient so that 2 acre-feet can be retained on each irrigated acre" and that a waste of 12½% should be provided to individuals over and

above that amount. This makes 27 in., which is comparable with the analytically determined duty for the Boise District of 30 in.

In conclusion, it is well to remember that no hard and fast rules can be laid down, and exact formulas cannot be devised. Such an analysis

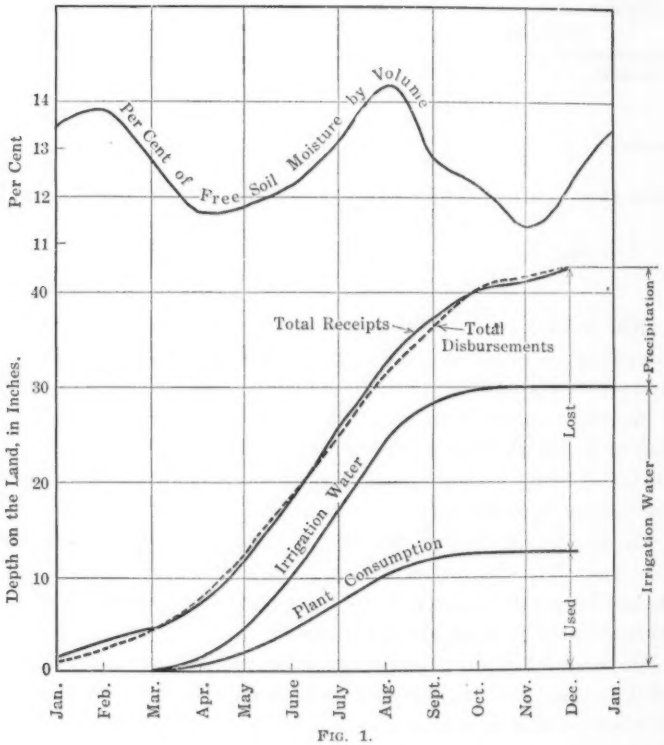

FIG. 1.

as that here outlined is a study in nice approximations in which consistency and common sense play important parts. Such analyses are necessarily based on the average, or mean climatic, year. No season exactly parallels the mean year. In dry years the quantity of irrigation water should, theoretically, be increased and during wet years it should be reduced. These yearly variations, however, can rarely be taken into

consideration in the design of irrigation works. The only practicable method is to base the design on the mean requirements and add a margin of safety for contingencies.

In the application of water to crops, there is a growing tendency to follow more scientific methods and thus eliminate unnecessary waste.

* Includes precipitation.

The amount of soil moisture is the best possible index of the necessity for irrigation and also of the amount to be applied. Heretofore this index has not been generally used because of the difficulty with which the amount of soil moisture could be determined. In this connection, it is perhaps fitting to add that the writer has recently designed a soil moisture indicator. This instrument is intended to be placed in the ground permanently, and indicates at the surface the relative amount of free moisture in the soil at any desired depth.

DISCUSSION

Mr. Means.

THOMAS H. MEANS,* M. AM. SOC. C. E. (by letter).—This paper was read the first time with considerable interest. It covers a subject in which all irrigation engineers are interested. The duty of water has long been a subject of discussion, and its determination is one of the most difficult problems which confront the investigator. Mr. Stevens has helped to systematize the analysis, but he has gone too far in attempting to place in mathematical form so intricate a subject. A closer reading of his paper reveals many statements that are unsound. In fact, the paper on the whole is a dangerous one for the man whose knowledge of irrigation is limited to a book acquaintance with the subject. It is not the desire to discourage such enthusiasts as Mr. Stevens, but papers of this nature should not go unchallenged and allowed to become a part of scientific literature, to be quoted by the parlor irrigators who fill the periodicals with wisdom on the subject, nor to become so well recognized as to be a factor in Court decisions on irrigation questions.

There is no more complicated subject connected with the business of irrigation than that of determining the duty of water. Soil, climate, crop, the irrigator, his practices, and time, all enter the problem. Each of these can be divided into a dozen or more sub-factors and to each of them can be assigned a part in the general result. Each factor and each sub-factor may vary without regard to the others, and the final result is far from being a simple matter, capable of solution by a formula so simple as that given by Mr. Stevens.

In the writer's opinion, the greatest error in Mr. Stevens' statement of what constitutes the net duty of water is that "percolation and surface waste are entirely under the control of the irrigator." He evidently has not had an opportunity of studying in much detail the physics of soil water, nor has he studied what becomes of the water which is applied to the land. The fact that deep percolation cannot be entirely controlled and that it varies in amount with different soils is the principal reason why the use of water in sandy and gravelly areas is larger than in heavier soils. There is no reason to believe that plant consumption is any greater in sand than in loam, but it is known that in practice it is difficult to maintain good growth in a soil of coarse texture with the same quantity of water as would be sufficient in loam soil. The inability of the irrigator to apply only the quantity which can be absorbed by the soil within the zone of root action causes more deep percolation in one type of soil than in the other.

Deep percolation is usually the most important cause of the waste of irrigation water. In some California districts, carefully planned

* San Francisco, Cal.

experiments have shown that 50% of the water received by the farmers passes below the zone of root action to such a depth that it cannot be recovered by capillarity. Improvements in methods of handling water will reduce, but not prevent, this loss. So impossible is it to prevent this deep percolation, even with the high duties now necessary in the San Joaquin Valley, that it is becoming the practice of irrigation engineers to recommend the installation of pumps to recover this underground water and thus add it to the supply. In two large districts, recently planned, it is proposed to recover, by means of wells, 20% of the quantity applied to the land, thus supplementing the original river supply. Mr. Means.

Many other points of Mr. Stevens' paper might be discussed, but they are evident to one familiar with this subject. He uses information which properly comes from the science of plant physiology. This is a science so far out of the realm of the civil engineer that the writer asked Mr. E. E. Free, formerly of the U. S. Department of Agriculture, to review the paper and give his views on the subject. His letter follows:

"The idea of Mr. Stevens' paper is suggestive. Regarded as purely hypothetical, which is, perhaps, the way Mr. Stevens intends it, it has interest; but it is very dangerous. Mr. Stevens derives and sets forth a series of mathematical formulas for the calculation of the duty of water. These formulas rest, admittedly, not on well ascertained facts but on assumptions, guessed at from such facts as are known. However necessary or justifiable this may be in an individual problem, where the maker of the assumption knows all the local circumstances, it is very dangerous as an attempt at general conclusions. There is danger of the common error of believing the mathematics and forgetting to scrutinize the assumptions.

"Although Mr. Stevens probably would not deny that his particular assumptions are of uncertain accuracy, it is perhaps of interest to suggest specifically some of these probable inaccuracies, especially where they concern or depend on the facts and probabilities of plant physiology.

"Mr. Stevens' final formula for the duty of water, Equation (7), involves the annual rainfall; the total annual percolation losses of rainfall and of irrigation water, respectively; the similar surface wastes or run-off; the total annual evaporation losses of rainfall, irrigation water, and soil water; and a factor, C, depending on the crop grown and called the 'total annual plant consumption'. This factor C is the same as that usually called the 'water requirement' and represents the quantity of water used by the plant during the production of one weight unit of dry matter.

"The most vital inaccuracy of Mr. Stevens' discussion lies in the assumption that this factor is, as he says (page 2106), a 'known, independent' quantity. It neither is 'known' in any general sense, nor is it 'independent' of all, or even of most, of the surrounding conditions. In the calculations for the Boise Project which Mr. Stevens includes, he

Mr. Means. uses values for the factor C derived from the experiments of Drs. Briggs and Shantz, at Akron, Colo. These experiments are admirable and are sufficiently conclusive for Akron and its immediate neighborhood. It is not claimed by Drs. Briggs and Shantz, nor is it probable, that the Akron factors could be used without change for other localities unless the climatic and other conditions were substantially identical. Indeed, the entire weight of experimental evidence is against such a general validity.

"The plant consumption or water requirement (Mr. Stevens' factor C) is the quotient of two rates: (1), the rate at which water passes into the plant; and (2), the rate at which the plant produces its own substance or 'dry matter'. This second rate is simply that of growth measured in weight units. Mr. Stevens appears to consider these two rates as mutually dependent, in such fashion that their quotient which is C, is a constant, at least when the agricultural results are reasonably satisfactory. He says (page 2096), 'every plant requires certain ideal conditions for optimum growth. These conditions involve a minimum water consumption.' If this is intended as a statement of a general fact, it is not true. A complete library of plant physiology would contain some tons of discussion concerning what is the 'ideal condition of optimum growth', but the facts established and agreed to could be written on a post card. Nor does any one of the 'optimum condition complexes' proposed by various meta-physiologists necessarily, or even probably, mean a minimum water requirement. These are strong statements and will be the better for being more specific.

"Remember that the plant consumption is determined by (1) the rate of water use, and (2) the rate of growth. The water use is partly water built into the plant tissues or metabolic water and partly water evaporated from the plant or transpiration. Usually transpiration is by far the larger. The quantity of water built into tissue does depend, obviously, on growth. Transpiration, or the water passing through the plant, however, depends only slightly on the rate of growth and mainly on the evaporating power of the air. The same plant placed in warm dry air may transpire, and, therefore, 'use' as much as five times the water which it uses in warm moist air. This change in transpiration may involve less than 10% change in growth rate, provided the temperature of the two environments is the same. The writer has observed this with potato plants.

"Plant literature contains many examples of the same purport. It is true that extremely dry air may limit growth as well as affect transpiration, but transpiration may vary widely before this extreme is reached and without the variation having any proportional or important effect on the rate of growth. Furthermore, this variation of transpiration is in response to a factor entirely external to the plant, namely, the evaporating power of the air, which does not importantly affect, nor is it affected by, the rate of growth.

"This is one instance of the lack of compensating changes in water use and growth rate, and, accordingly, of lack of constancy in the factor C. Other instances of effects on one of the elements of C, without compensating effects on the other, are:

Mr. Means.

"(1) The effect of temperature on growth rate;
(2) The effect of sunlight, and hence of photo-synthetic foods, on growth;
(3) The unbalanced effects of varietal and other variations in plant composition, especially sap concentration and acidity, on both growth rate and transpiration;
(4) The effect of the character of leaf surface, for instance, dust or water films, on transpiration;
(5) The effect of the capillary pull of the soil on the saturation deficit in the plant and thence on both transpiration and growth, but in unequal measure; and
(6) The effect of root condition, especially as modified by soil aeration, on transpiration.

"The conclusion is that the water requirement—the factor *C*—is a very complex thing. It is affected importantly by nearly every feature of the environment, and it is in the highest degree unsafe to apply to one locality numerical factors obtained in another locality. Hence the assertion that Mr. Stevens' factor *C* is neither 'known' for any area in which it has not been actually determined, nor is it 'independent' of the environmental factors of each locality. It would be scarcely less justifiable to predict the rainfall of Chicago, Ill., from the records of Washington, D. C., or New York City.

"The error of assuming greater definiteness than the present knowledge permits applies also to several other features of Mr. Stevens' calculations. Thus, Formula (1), which gives the proportion of the rainfall evaporated, is admittedly only a guess, and will be affected by wind velocity and relative humidity, neither of which appears in the formula. Formula (2), which gives the evaporation from the soil, is presented with 'the only claim for it is that it approximately fits the results of Lee's experiments in Owens Valley', obviously, a slight enough basis for general use, especially since Owens Valley is climatically unusual. Furthermore, Mr. Stevens' discussion preceding the presentation of this formula contains two serious errors. The first is that the percentage of capillary moisture in the soil is proportionate to the height above the water-table. This neglects entirely the nearly general fact that the soil texture varies between the subsoil, the soil proper, and the surface layer of soil. The second error is that the amount of evaporation from the soil is a function of its temperature and water content. This neglects the aerial factors of relative humidity and wind movement and the terranean factors of the artificial or natural creation of a dry mulch, the rate of movement of capillary water, and the diffusion of water vapor through the surface soil. The formulas for percolation and surface losses are open to uncertainties of the same kind and would require for their acceptance the presentation of many times more experimental data than is contained, or referred to, in Mr. Stevens' paper or in the generally known literature.

"Equally erroneous, though less vital to the argument, are the assumptions on page 2104 that the wilting point and optimum water content are independent of the aerial environment, and the statement on page 2096 that: '4.—Transpiration varies almost directly with the

Mr. Means. saturation deficit (*i. e.*, 1—relative humidity)'. The first assumption has been disproved by Caldwell, and the statement concerning transpiration ignores what is the greatest single factor in practice, namely, wind. It is no less an error, however unimportant practically, to regard hygroscopic, capillary, and gravity water as distinct in behavior, as Mr. Stevens apparently does on page 2095, or to say that hygroscopic water 'is not available for plant growth'. Water in the soil cannot be separated into kinds or classes and whether or not hygroscopic water is available to plants depends on the soil, the plant, the environmental conditions, and whatever definition of hygroscopic chances to have been adopted. Mr. Stevens' definition means little, since it includes the terms, artificially heated, moist air and cooling, none of which is intrinsically definite and none of which is defined.

"To summarize: Mr. Stevens has attempted a precision and generality which the facts do not justify. When Science is ready, if ever, to state a mathematical formulation of the duty of water, that formulation will be much more complex than that given by Mr. Stevens. At best, he has attempted something which is impossible at present. At worst, he is preparing to rely (and, perhaps, to have others rely) on conclusions which may be sorely misleading if applied generally. There is a gentleman of the American stage who possesses the knack of sitting down on a chair which is not there. This is a dangerous accomplishment in science. One may forget some time that the chair is hypothetical; but there will be no mistaking the reality of the bump."

Mr. Horton. ROBERT E. HORTON,* M. AM. SOC. C. E. (by letter).—Inasmuch as the term "duty of water" is used mainly in irrigation districts, and no definition thereof is given by the author, it seems worth while to call attention to a somewhat peculiar usage of this term.

The word "duty", in irrigation practice, seems to be used in the sense of "duty performed". It is measured in terms of the depth of water required to produce an agricultural crop on irrigated land. In some respects it resembles the reciprocal of the term "efficiency", the latter being the ratio of work performed to energy supplied. "Duty", however, is a much less definite term than "efficiency" in that, as usually applied, it is not a ratio of the quantity of water supplied to the quantity of crop produced, but merely the quantity of water supplied to produce a crop. Theoretically, and in some discussions, the word "duty" is applied as meaning the quantity of water which will produce the best crop on given land. For a quantitative determination of the water requirement for irrigation, it seems desirable that some more definite term should be devised and used. Messrs. Briggs and Shantz, as well as others, have used the term "water requirement ratio" to express the ratio of the weight of the water consumed by transpiration to the weight of dry matter produced by vegetative processes. The water requirement ratio varies somewhat widely for different

* Voorheesville, N. Y.

Mr. Horton.

plants or crops, and inasmuch as transpiration is one of the principal water losses involved in irrigation, it is evident that the duty of water in irrigation must vary according to the nature of the crop produced, other things being equal. There are so many variables that, as duty is ordinarily expressed, comparisons of the duty of water in irrigation from determinations for different crops in different localities have hitherto had but little meaning.

Like other branches of applied hydrology, irrigation, is passing from the era of "rule-of-thumb" methods of pioneer practitioners to a more scientific basis of procedure. It is certainly to be desired that the various elements involved loosely in the term "duty of water" should be rendered capable of more definite measurement and comparison. The author's paper is a preliminary step toward the accomplishment of such a result. As a tentative suggestion, the expression of results obtained in irrigation by means of what may be called "irrigative efficiency" seems worthy of consideration. Assume for purposes of discussion that to produce a unit weight of dry vegetable matter with a given kind of crop requires the consumption through transpiration of at least a certain minimum volume of water, then if the total weight of dry matter of the crop produced per acre is known, the total volume of water, expressed in acre-inches, required to supply the needs of transpiration can be determined from the water requirement ratio. The "irrigative efficiency" is the ratio of the minimum quantity of water required to supply the needs of transpiration to the total quantity of water supplied to the area under cultivation.

Data regarding the water requirement ratio for most crops grown on Western irrigation lands are supplied by the experiments of Briggs and Shantz, and others. As will be pointed out, these data are not altogether satisfactory for direct application, since the water requirement ratio apparently is not constant for a given drop, as many experimentors on this subject appear to have assumed. However, using the water requirement ratio as the best basis at present available for estimating the net actual water requirements of different crops, it is easily possible to determine the irrigative efficiency of a given field and crop, if the depth of the water applied is known—furthermore, the irrigative efficiency seems to afford a very much more definite and scientific basis of comparison of the results obtainable by irrigation of different crops, and on different lands, than the indefinite term "duty of water."

Given the irrigative efficiency for one crop and area, the depth of water required is readily obtained. As an example of the application of this term, consider the growth of a crop of wheat, yielding 25 bushels per acre, on irrigated land. The water requirement ratio for spring wheat, from the experiments of Briggs and Shantz, is 1 350, that

Mr. Horton.

is to say, the weight of water lost by transpiration and consumed in vegetative processes is equal to 1 350 times the weight of dry matter, including grain and plants, above ground. Using an average ratio of weight of grain to total weight of dry matter produced above ground, and reducing these figures to equivalent inches depth of water on the surface per bushel of grain, the value of this ratio becomes 0.358. In other words, the water requirement ratio is 0.358 acre-in. per bushel of wheat per acre, or 8.95 in. depth for a yield of 25 bushels per acre. If, now, the total depth of water applied is 24 in., for example, the irrigative efficiency is 0.373.

This method leads to another useful result, as it shows at once the quantity of water applied which serves no useful purpose. The actual water requirement being 8.95 in., the irrigation losses are $24 - 8.95 = 15.05$ in.

The two questions which most concern the irrigation engineer are: (1) What becomes of this waste? and (2) By what modes of procedure may the water losses be reduced, and the irrigative efficiency consequently increased?

Now, if the crop had been 20 bushels instead of 25 bushels per acre, the duty of water, as ordinarily defined, would have been the same as before with the same depth applied, but the irrigative efficiency in the latter case would have been 30 instead of 37 per cent. This may have been the result of poor farming methods, poor methods of applying the irrigation water, unfavorable weather for crop growth, or lack of under-drainage. This example illustrates the ineptness of the expression "duty of water". It involves the effect of various factors which have to do only indirectly, if at all, with the efficiency of the water applied in crop production.

The author omits one form of water loss, namely, interception, or rainfall which is evaporated without reaching the ground. This factor is of much greater importance in relation to run-off or dry land agriculture than in relation to irrigation. However, in an irrigated region, where the rainfall is, say, 10 in. during the growing season, the loss by interception may be from 1 to 2 in.

The author distributes transpiration losses in direct proportion to the mean monthly temperature minus 32 degrees. This method, while simple, does not appear to be fully justified. It is true that transpiration per unit area of plant surface is closely correlated to air temperature, but simply for the reason that transpiration is essentially an evaporative process, and evaporation is more closely correlated to temperature than to any of the other factors affecting it. The transpiration rate is more closely correlated to evaporation than to temperature, and, therefore, the latter appears to be the better basis for distribution of the monthly amounts. This is illustrated by Table 12,

which shows the correlation coefficients between the transpiration rate for various crops, and various meteorological factors, as determined by Messrs. Briggs and Shantz. Mr. Horton.

Transpiration depth in inches per month for any crop is the product of the transpiration rate per unit surface multiplied by the area of transpiring surface. The latter increases as the crop grows. The rate of growth is a close function of effective temperature. The effective temperature in relation to the growth is generally accepted by botanists as being the excess above 41° Fahr. After the plant reaches maturity, and during the ripening period, the transpiration rate decreases.

The total transpiration surface, therefore, is approximately a function of the cumulative temperature in excess of 41° Fahr., starting at the date when the crop appears above ground; however, transpiration is not exactly proportional to area of plant surface, but is less for mature than for young vegetable tissues, so that, as shown by the experiments of Messrs. Briggs and Shantz, J. W. Leather, and others, the transpiration rate per plant under constant weather conditions follows approximately a sine curve, as also does temperature. If, therefore, transpiration rate is to be expressed as a function of temperature, it should be proportional to some power of the air temperature higher than unity, since it is a product of two factors, both accidentally, or otherwise, functions of temperature.

A better method of distributing monthly transpiration loss seems to be as follows: (1) Calculate the evaporative capacity, which can be readily done from meteorological data usually available; (2) to obtain the relative transpiration loss, multiply the evaporative capacity for each month by the transpiration-evaporation ratio. Fortunately, these ratios are much alike for most ordinary crops. Numerous values of the transpiration-evaporation ratio for different crops and plants have been worked out by Messrs. Briggs and Shantz, J. W. Leather, B. E. Livingston, and others, from whose published results the requisite data for the application of this method can be obtained.

Mr. Horton.

The author has given some attention to the matter of the quantity of infiltration. It is surprising that in view of the great importance of infiltration as a factor in all matters involving the hydrologic cycle so little attention has been devoted to the subject. Aside from meager experimental data by Messrs. O'Meara and O. R. Mathews, nothing bearing directly on this subject appears to have been published in English. It seems worth while, therefore, to consider the nature of infiltration.

In the first place, infiltrated water supplies: (*a*) The ground-water which runs off in streams; (*b*) practically the entire transpiration requirement of vegetation; and (*c*) such portion of the evaporative loss from soil surfaces as is comprised in capillary evaporation. This is usually the larger portion of soil evaporation, because at other times than during rainfall the supply of water for evaporation from soil surfaces is mainly derived from previously infiltrated water through capillary uplift.

It may be inferred from one of the author's statements, and is perhaps popularly believed, that infiltration does not take place when the ground is frozen. The writer's experience is to the contrary. If a soil which is more or less sandy becomes frozen at a time when it is not thoroughly saturated, infiltration will take place through such a soil, even though it may be frozen to a depth of several feet. The writer has observed this condition repeatedly, and the concordant rise of ground-water levels. This sometimes takes place without the frost going out of the soil to any appreciable degree.

Apparently, infiltration increases rapidly with the temperature, as would be expected from experimental results of the flow of ground-water such as those of Mr. Charles S. Slichter. At any rate, the proportion of the total rainfall which is infiltrated during the early spring and late fall is very much less than the proportion which is infiltrated during hot midsummer weather. The surface run-off in the early spring and late fall is accordingly larger. It is this fact which mainly accounts for the prevalence of floods during the spring and fall, even in the absence of melting snow, whereas equal or heavier rainfall in midsummer months is mostly infiltrated and causes but little surface run-off. It is true that the difference in midsummer conditions and conditions in cooler weather, in this regard, is often attributed to evaporation. Simple calculations will show, however, that evaporation plays a less important part than infiltration.

For example, consider a three-day storm in April or early May, with a total precipitation of 4 in., and a similar three-day rain in August, the stream being at about the same initial stage in both cases, and the drainage basin sodded. In the spring rain, the total interception and soil evaporation losses during the rain amount to, perhaps,

Mr. Horton.

½ in. Of the remaining 3½ in., on a suitable area, about 1 in. will be infiltrated, leaving 2½ in., or 62.5%, to run off the surface, this being sufficient to produce severe flood conditions on many small drainage basins. In midsummer the interception and evaporation loss during the rain may amount to 1½ in. for the three-day period. Of the remaining 2½ in., at least 2 in. will be infiltrated on most classes of cultivated areas, leaving only ½ in., or 12.5%, for surface run-off, or insufficient, as a rule, to produce flood conditions.

This statement is made for illustrative purposes only, but the difference therein indicated is believed to be realized.

The author gives a number of formulas for calculating the evaporation from the soil. The formulas undoubtedly contain the correct factors, or at least they contain factors closely correlated with those which actually control the processes; however, these formulas appear to be not only empirical but arbitrary, and it is doubtful if the factors given are in their correct relations. There is room for great advance in the hydrology of soil moisture in relation to agriculture, and the author's treatment of the subject is at least suggestive, even though it may demand marked revision.

The writer uses the formula:

$$E_s = E_w\, r$$

for calculating evaporation loss from soils. E_w is the "evaporative capacity" for a water surface having at all times a temperature equal to the soil surface, and otherwise similarly disposed. The writer has given a formula* for calculating evaporation or evaporative capacity. Subsequent experience in applying this formula to measured evaporation, as determined at thirty-five, Class A, U. S. Weather Bureau Stations, indicates that it gives very reliable results.

Buckingham has shown, and the experience of others indicates, that evaporation from the surface of a soil, other things being equal, bears the following relation to evaporation from a water surface in the same environment:

$$\frac{E_s}{E_w} = r.$$

where r is the "saturation ratio", or moisture content of the soil, expressed as a ratio to its moisture content when fully saturated or "imbibed". B. A. Keen concludes that evaporation from the soil is not directly proportional to the saturation ratio. His experiments, however, indicate that over the ordinary range of soil moisture conditions and for most soils, the assumption of direct proportionality will give at least approximately true results.

* *Engineering News-Record*, April 26th, 1917, p. 917.

Mr. Horton.

J. W. Leather has suggested the use of the exponential or compound interest law, which may be written

$$r = K_c e^{-bt}$$

for calculation of soil evaporation after rain or irrigation.

In this connection, it may be added that Buckingham's conclusion that soil evaporation is proportional to moisture content leads, under certain simple assumptions, directly to this formula for the evaporation ratio, $\frac{E_s}{E_w}$, during the time interval, t, after saturation.

The extensive experiments of Samuel Fortier, M. Am. Soc. C. E., on evaporation from soils after irrigation, give results which can be quite accurately represented by a formula of the exponential type.

The writer believes that this formula, while substantially correct and undoubtedly the simplest and best which can be used in practice, is nevertheless empirical, and not the precise or at least not the complete form of expression. This conclusion is reached from certain theoretical considerations which cannot be fully presented here for lack of space.

This paper is particularly interesting, because it represents an attempt—perhaps the first published attempt—to apply the rational water-loss method to the quantitative determination of irrigation requirements. The water-loss method of estimating the available yield of drainage basins has long been in use in a somewhat restricted form in England, and, of late, its use has progressed rapidly in the United States.

The writer has applied throughout a number of years methods of estimating stream flow closely analogous to the author's method of estimating irrigation requirements. However, the development of the same method for different purposes, and in different regions, has naturally led to different formulas for calculating the chief elements involved.

In conclusion, it appears that one of the things most needed in order that water-loss methods may be developed on a practical working basis is the determination of necessary factors and coefficients in relation to infiltration, soil moisture, and capillary flow, evaporation under the shelter of trees and crops, and transpiration rates for trees and natural vegetation other than cultivated crops. These factors, at least some of them, can be determined by an analysis of existing records of precipitation and run-off on drainage basins. When a sufficient body of carefully prepared data of this type becomes available, better estimates of water losses can undoubtedly be made.

Mr. Stevens.

J. C. Stevens,* M. Am. Soc. C. E. (by letter).—The author is grateful to Mr. Means and Mr. Free for their joint criticism of his

* Portland, Ore.

paper. He would even be more grateful if they had caught the spirit and the purpose of it. For their benefit and for that of others who may give the paper a cursory reading, the author begs to quote from the beginning of his paper: Mr. Stevens.

"The object of this paper is to strip this subject of some of the ornate generalities that usually characterize its discussion, and to suggest lines along which future research should be conducted in order to supply the missing data necessary to the solution of the problems."

and again from the closing:

"In conclusion, it is well to remember that no hard and fast rules can be laid down, and exact formulas cannot be devised. Such an analysis as that here outlined is a study in nice approximations in which consistency and common sense play important parts."

The author is fully aware of the very complex nature of every factor entering into a determination of the duty of water. They are so complex, in fact, that their individual effects have not been used, except in the most general manner, in arriving at a duty of water for any particular locality and set of conditions.

It is useless to deny that in the past the duty has been fixed largely by guess, aided of course by the experience and judgment of the guesser, and in guessing the one factor which, perhaps, has been given the greatest weight is the available water supply—a human factor, and not a physical one.

Mr. Means says that in his opinion the statement that "percolation and surface waste are entirely under the control of the irrigator" is greatly in error. He failed to bring out the author's qualifying statement which is found on page 2102:

"It has been thoroughly demonstrated in practice that the quantity of irrigation water lost by percolation is entirely under the control of the irrigator, provided his supply is sufficiently elastic to permit him to adopt the proper methods of application."

This involves the human factor to such an extent that it is well to examine briefly what practice has demonstrated. Some truly wonderful results are being secured in localities where only a very limited supply is available.

It has been often demonstrated, both by experiment and in practice, that in order to save water from percolation and surface waste on porous soils, the supply must be such as to permit quick application of small quantities at frequent intervals. It would almost seem superfluous to go into this matter further, but inasmuch as Mr. Means has branded the author's paper as a "dangerous one", a few facts will be presented in the hope of convincing those who might assume that the author's conclusions have been hastily drawn.

The Hood River District of Oregon and the Underwood District of Washington are on opposite sides of the Columbia River. Condi-

Mr. Stevens.

tions of soil and climate are probably as nearly identical as it is possible to secure. In the Underwood District water is pumped to a height of 600 ft. The Hood River District has an abundant gravity supply.

In 1917, the water actually applied to certain representative tracts in the Hood River District, was measured by the State Engineer, as follows:

Tract.	Water applied (depth, in feet).	Yield.
Ia	4.86	2.80 tons clover in orchard
Ib	2.02	2.74 " " " "
Ic	6.58	3.11 " " " "
II	11.0	5.00 " " " "
III	7.13	not measured
IV	2.98	2.00 tons alfalfa in orchard

The average depth applied in the entire district of 19 000 acres was 3.3 ft.

In the Underwood District the total supply per season is limited to about 1.2 ft. in depth. Doubtless, the yields in the Underwood District are not as great as across the river, but there is no question that even with this limited supply, farming has been highly profitable. With the farmers in this district it is simply a question of 1.2 ft., or none at all. They are driven by necessity to economize to the fullest extent. In the Hood River District necessity does not so demand, and larger quantities are used. Now, this difference in water duty for the two districts is not one of physical conditions, but a difference in human endeavor pure and simple. Almost every engineer who is at all familiar with irrigation practice, can cite similar examples. The fact that large quantities of water are lost by percolation is due in most cases either to an indifference on the part of the irrigator or else to the fact that his supply is so inelastic that he could not adapt proper methods if he desired.

The saving effected by proper methods of application is well shown in Bark's experiments in Idaho.* Tanks, 6 ft. deep, were filled with the original soil from the middle of an alfalfa field by means of which the quantity of water percolating beyond the root zone was definitely measured. The tanks were cropped with the same alfalfa grown in the field.

In 1911 the same quantity of water was applied to the tanks as the farmer applied to his field, no attempt being made to alter the farmer's practice. The field and tank were irrigated seven times, applying a total of 6.6 ft. with a loss of 5.5 ft., or 84%, by percolation. The results are given in Table 13.

* Ninth Biennial Report of the State Engineer of Idaho.

Mr. Stevens.

Deducting the amount of percolation and evaporation, it was found that 411 lb. of water were required to produce 1 lb. of cured hay, considerably less than was used in the calculations for the Boise District.

It was also found that only 0.15 ft. was retained in the soil at each irrigation. Accordingly, the following year the tanks were irrigated with about this quantity as often as the alfalfa appeared to need water, with the results shown in Table 14.

This shows that practically all the percolation was saved by applying small quantities frequently. In 1911 the plants snatched their

Precipitation	0.31	.....	....	..	.....
Total received	6.91	.....	....	80	.....

supply from the water as it passed downward past their roots. In 1912 only the quantity was supplied that the plants required. The result was an average yield of 3.25 tons per acre in 1911, with a consumption ratio of 411 to 1, while in 1912, with a consumption of 380 lb. of water per pound of cured hay, the yield was 7.1 tons per acre.

A great saving is also effected by reducing the "length of run." By the "length of run" is meant the distance from the supply ditch to the farther end of the field. When water is supplied from a head ditch, the soil near the ditch unavoidably receives more water than that farther away. In order to irrigate properly the lower end of a field it is necessary to over-irrigate the supply end. By using a larger "irrigation head" and shortening the length of run by dividing the field by additional supply ditches a great saving may be made in the quantity of water used and in the time required for complete irrigation.

Fig. 2 shows the effect of the length of run on two fields experimented on by the U. S. Reclamation Service near Boise, Idaho, in 1910 and 1911. Fig. 2 (*b*) and (*c*) shows the saturation diagram when the

Mr. Stevens.

attempt was made to saturate the ground to certain depths. As shown by Fig. 2 (*b*), to saturate the lower end of the field to a depth of 2.5 ft. required its saturation to a depth of 6.5 ft. at the upper end. If the tract had been subdivided into four equal parts by three additional supply ditches, the upper end of each tract need only have been saturated to a depth of 3.5 ft. As shown by Fig. 2 (*c*), to saturate to a depth of 4.4 ft. at the lower end required a saturation of 12.4 ft. at the upper end, with a single run, or 6.4 ft. for each tract if subdivided.

The water saved by reducing the run in Fig. 2 (*b*) was 26%, and

Total received	2.34	.....	.....

36% in Fig. 2 (*c*). To effect these changes, larger irrigation heads for shorter periods of time are required. In Fig. 2 (*a*) is shown the duration and water consumption curves for these tracts to obtain the same degree of saturation.

For example, when Tract No. 9 was saturated in 10 hours, 2.5 acre-ft. were required, but if 30 hours were consumed with a smaller head, then 3.7 acre-ft. were required to produce the same minimum degree of saturation.

Don Bark has also included the effect of length of run in his excellent experiments. Two tracts were used: First, a strip of clover, 50 ft. wide and 2 359 ft. long; and second a strip of alfalfa, 92 ft. wide and 2 566 ft. long. The first tract was divided into seven equal parts. A constant irrigation head of 3.0 sec-ft. was turned in at the upper end to flood the strip. The time required for the water to travel to the lower end and thoroughly irrigate each division was observed. In the second case an irrigation head of 7.0 sec-ft. was used. The results are given in Table 15. This table shows that twice the water and twice

the time would be required to give this ½-mile strip the same degree of irrigation in a single run over that were it divided up into ⅛-mile runs by additional supply ditches. Mr. Stevens.

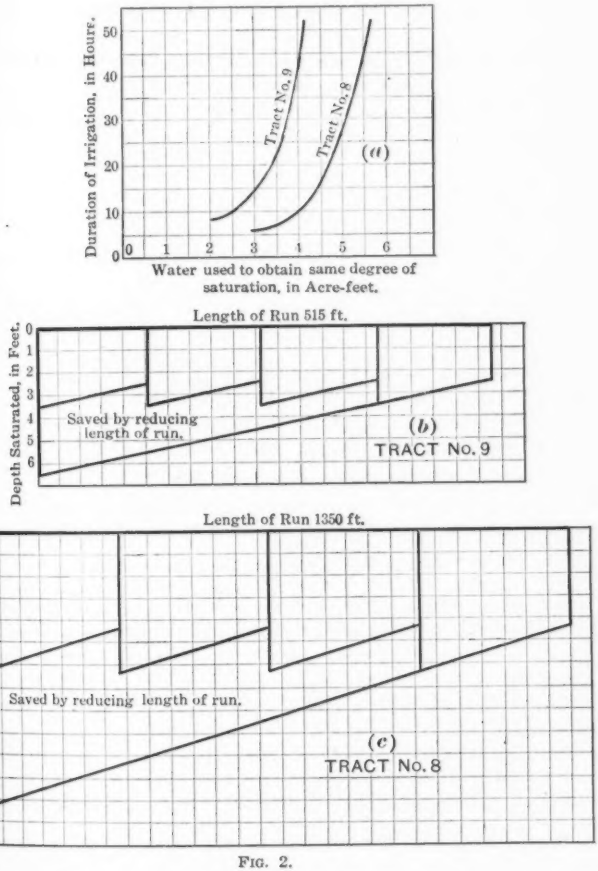

FIG. 2.

Table 16 shows similar results. With the length of run reduced to ⅛ mile, only half the water and less than half the time was required to attain the same minimum degree of irrigation over that for ½-mile runs.

The great saving that may be secured by a proper control of the human factor in irrigation practice has been demonstrated so

Mr. Stevens.

thoroughly that the author feels the truth of his statement that surface waste and percolation losses are under control, and that evaporation losses are partly under the control of the irrigator, provided his supply is sufficiently elastic to permit him to adopt proper methods of application, has been demonstrated too thoroughly to merit further discussion.

TABLE 15.—EFFECT OF LENGTH OF RUN ON PERCOLATION FROM CLOVER FIELD USING IRRIGATION HEAD OF 3.0 SECOND-FEET.

2 022	1.26	14.50
2 359	1.47	15.67

Mr. Free has also failed to grasp the purpose and spirit of the author's use of plant transpiration as a factor in determining the duty of water. This quantity, designated as C in Equation (7), is known and independent only in the sense that it was determined prior to its inclusion in the formula. This is so evident from the treatment of this factor in the paper that it almost seems superfluous to call attention to it.

TABLE 16.—EFFECT OF LENGTH OF RUN ON ALFALFA FIELD USING IRRIGATION HEAD OF 7.0 SECOND-FEET.

Length of run, in feet.	Average depth on entire tract, in feet.	Time required to irrigate entire tract had it been divided as shown, in hours.

2 287	1.17	11.8
2 566	1.33	13.3

Any one who will study the classic experiments of Briggs and Shantz, and others, on the water requirement of plants will emerge from their study with the conviction that this factor is even more complex and more dependent on all environmental conditions than Mr. Free has pointed out. To the plant physiologist these fine distinctions are doubtless of absorbing interest, and he no doubt "views with alarm" any attempt to make practical use of the data.

Mr. Stevens.

The author believes that out of all this maze of complexity some probable value for the plant consumption of standard grains, forage, and other crops can be determined sufficiently approximate for its inclusion in duty of water determinations; especially so, when it is realized that of the total quantity of water applied, only about one-third is used by the plant, the remainder being considered as necessary losses. As convincing proof of this statement one has only to consider the crops grown in humid regions where the water received is quite generally less than that applied under irrigation. Where water is supplied to crops by rainfall, the same factors of evaporation, percolation, surface run-off, and plant consumption in varying degrees, are involved, all within a less total depth, or duty, than is involved under irrigation. How, therefore, can the total plant consumption, involved factor though it may be, vary so greatly that approximate limits cannot be fixed for it within a "middle third" of the total duty? Must one who attempts to bring a little order out of chaos or to inject a bit of practical husbandry into "optimum condition complexes" be branded as an "enthusiast" and a "parlor irrigator" and his efforts as "purely hypothetical" and "very dangerous"?

The author is well aware of the looseness of the term, duty of water, as Mr. Horton points out. However, if one attempted to follow his suggested use of the term "irrigative efficiency" he must be able to fix with much greater definiteness the water requirement ratio than the author thought was justified by present knowledge of the subject.

It is to be hoped that further research will be along lines that will lead to a more general knowledge of this factor, so that its limits for various localities and crops can be better known. As a matter of pure science, an exhaustive study of all environmental and varietal influences are vital and necessary, but the agriculturalist is interested in something broader. Approximate quantities are sufficiently accurate for his purpose.

As used in the paper the term "duty of water" is intended to mean the quantity that an irrigator should have at his disposal in order to produce his crops under the average conditions of his environment. It is not the least with which the expert farmer can get along, nor the quantity the "water hog" would like to have.

The human factor enters so largely into the problem that, for a majority of localities, at least, if water could be metered to the irrigator and he was charged for what he consumes on a basis that would induce economy of use, the perplexing question of what was the proper duty for that locality would be automatically solved.

MEMOIRS OF DECEASED MEMBERS

FREDERIC PIKE STEARNS, Past-President, Am. Soc. C. E.*

DIED DECEMBER 1ST, 1919.

The life of Frederic Pike Stearns is a fine example of steady progress to the highest professional attainment, through persistent and well directed effort. It should be an inspiration to many engineers.

Frederic Pike Stearns, the son of William Henry Clark Stearns and Mary (Hobbs) Hill Stearns, was born in Calais, Me., on November 11th, 1851. He came of sturdy New England stock, having been a lineal descendant of Isaac Stearns, who came to this country from England as a member of Governor Winthrop's party and settled in Watertown, Mass., in 1630.

Mr. Stearns' early training was received in the public schools of his birthplace and was followed by a very brief business experience there. Like many another bright and active boy, he soon determined to seek the greater opportunities of the large city, and in his eighteenth year he went to Boston, Mass., to begin his education in the field of civil engineering.

He entered the office of the City Surveyor of Boston at a time when municipal engineering was in its infancy in the United States, and when the first great water-works and sanitary systems were being projected. His lack of preparation and experience would have been an unsurmountable barrier to success but for his industry and determination to fit himself to meet his task.

He began to study intensively along scientific lines, in his evenings and other spare moments, and soon attracted the attention of a notable group of engineers, then leaders of the profession in Boston, among whom were the late J. P. Kirkwood, E. S. Chesbrough, James B. Francis, Past-Presidents, Am. Soc. C. E.; Charles S. Storrow, Hon. M. Am. Soc. C. E., and Joseph P. Davis, M. Am. Soc. C. E.; and Hiram F. Mills, Hon. M. Am. Soc. C. E.

Growing in mental vigor and professional stature, Mr. Stearns soon became a leader and throughout his life was attracted by and drew about himself in his work men of strong character and alert, studious, and constructive minds, men who have played important parts in the development of municipal and sanitary engineering in the United States and abroad. Self-trained in sound and logical thinking, with an acquisitive mind, Mr. Stearns constantly broadened in vision through contact with Nature and man, calling to his assistance in his

* Memoir prepared by Leonard Metcalf, M. Am. Soc. C. E.

professional work the chemist, biologist, and bacteriologist, the geologist, architect, and landscape gardener, as the interrelation of his field and theirs became apparent to his pioneer mind—himself responding to their fresh stimulus, growing in judgment and balance, and reflecting the friendly attitude and nice courtesy of master minds to one another.

From 1872 to 1880, under the late Joseph P. Davis as Chief Engineer and Alphonse Fteley, Past-President, Am. Soc. C. E., as Resident Engineer, he served as Leveler, Assistant, and then Division Engineer in the Engineer Corps of the Boston Water-Works, having been engaged on the investigation and, later, the construction and maintenance of the additional water supply from the Sudbury River, for the City of Boston. During this period, with Mr. Fteley, he carried out an important series of hydraulic experiments on the flow of water through this conduit and over weirs, and presented the results in a paper before the Society in 1882, which won the Norman Medal, and in two subsequent papers.*

In 1880 Mr. Stearns was transferred to the Main Drainage Works of Boston, as Division Engineer in immediate charge of the tunnel under Dorchester Bay and the reservoir and other outlet works at Squantum and Moon Island, under Joseph P. Davis, City Engineer, and, later, his successor, the late Henry M. Wightman, M. Am. Soc. C. E., and with Eliot C. Clarke, M. Am. Soc. C. E., Principal Assistant Engineer. A part of his time was also devoted to the preparation of plans for the Sudbury Aqueduct crossing Farm Pond, the high-service reservoir on Fisher Hill, and a sea-wall on the Charles River Basin Embankment. From the summer of 1885 to 1886, as Executive Engineer, he had charge of the whole Main Drainage System and for a portion of this time acted as Engineering Assistant to a commission on the prevention of floods in the Valley of Stony Brook, consisting of the late Mr. James B. Francis, Mr. Eliot C. Clarke, and Clemens Herschel, Past-President, Am. Soc. C. E.

It is a noteworthy fact that these Main Drainage Works still stand as a monument of good engineering, modified only by extension to meet the growth in the district served, during this 35-year period.

In 1886 Mr. Stearns was called to the position of Chief Engineer of the Massachusetts State Board of Health. This Board

"had just been reorganized by the Legislature and, upon the recommendation of a commission of far-seeing citizens, of which the late John Quincy Adams was Chairman, had been charged with the oversight and care of the inland waters of the State and given the power to advise its municipalities and citizens upon all matters pertaining to water supply, drainage and sewerage and the prevention of the pollution of inland waters for the purpose of protecting the public health, promoting comfort and improving the living conditions of its

* See page 2137.

inhabitants. The remarkable body of able men charged with this responsibility, under the leadership of Dr. Henry P. Walcott, Chairman of the Board, and the inspiration of Mr. Hiram F. Mills, its engineer member, gathered around them the most notable group of practical scientists which had ever up to that time been associated for public health work. The work of the Board was new, no precedents existed, and the law under which the work was carried on attached no penalty in case of neglect or refusal to follow its recommendations or abide by its decisions. These decisions, in the language of those who planned this new departure in public service, were to 'look for their sanction to their own intrinsic sense and soundness', and the great influence in all matters pertaining to its work which the State Board of Health quickly acquired was due in great measure to the thoroughness and sound judgment, combined with the tact and fairness, of its chief engineer. His keen and exhaustive study of the water supplies of the State set a new standard for scientific investigations, while his tact in dealing with officials with whom he came in contact and his steadfast courage in insisting upon the right course of action secured the confidence of the public in the findings of the Board and established a means of controlling and improving the water supplies in Massachusetts which has become the basis of the practice in other States.

* * * *

"Among his notable contributions to general knowledge made in this period were his studies of stream flow and storage, establishing the principles of the economical development of the yield of water-sheds which were afterward used generally by the engineers of New England."*

During this nine-year period Mr. Stearns investigated and reported on a comprehensive sewerage system for the Mystic and Charles River Valleys, outlining plans, which were promptly approved and ordered executed by the Massachusetts Legislature; and as Chief Engineer to a Joint Board, consisting of the Massachusetts State Board of Health and the Metropolitan Park Commissioners, on the improvement of the Charles River, he recommended the construction of a dam, with a tidal lock, near Craigie Bridge, to create a fresh-water basin to be maintained at a constant level, though no work was done on it for some years. By this project, which was also exhaustively studied and reported on at a later date by John R. Freeman, M. Am. Soc. C. E., a life-long friend of Mr. Stearns, and which was subsequently executed under Hiram A. Miller, M. Am. Soc. C. E., Chief Engineer, with Mr. Stearns as Consulting Engineer, the foul estuary of the Charles River, with its tidal flats, was converted into a beautiful fresh-water basin, completely changing the character of the district and becoming one of the great recreation waterways and parks of the United States, affording badly needed relief to the congested population to the east of it.

* From Memoir of Mr. Stearns prepared by X. H. Goodnough, M. Am. Soc. C. E., for the New England Water Works Association.

In the early Nineties, Mr. Stearns came into contact with, and was much impressed by, the work on the Metropolitan Parks around Boston of the well-known landscape architect, Mr. Charles Eliot, of the firm of Olmsted, Olmsted, and Eliot, and this doubtless influenced him in his later work.

The most important work done by Mr. Stearns for the Massachusetts State Board of Health was the investigation and report on a Metropolitan Water Supply to serve the City of Boston and a large district about it, which he completed in 1895. This was the fruition of his long and close study of the water-supply problem. He, as probably no other man, sensed the need and the opportunity. He knew the state of the art and the progress of public opinion on the water-supply problem. He had helped to mould the latter along sound lines, impersonally, and with bettered service always in view, and in thus doing had won unasked the confidence of the public. Thus, naturally, there fell to him the task of building the new works.

Between 1895 and 1907, as Chief Engineer of the Metropolitan Water Board and its successor, the Metropolitan Water and Sewerage Board, he welded and inspired the engineering organization which gave effect to his ideas and built his greatest monument—the complete system of water supply for the City of Boston and nineteen surrounding municipalities, comprising great and noble dams in masonry and earth, reservoirs, aqueducts, pumping stations, and pipe systems. It may justly be said of them that they were conceived with a foresight and executed with a skill guided by the hand of Nature herself. Their worth has been demonstrated by two decades of good service. They constituted what Mr. Freeman has characterized as being at the date of their construction probably the most noteworthy series of water-works structures in the United States; foremost not altogether in size, but in perfection of detail and the embodiment of the best practice in hydraulic engineering throughout, from reservoir to pumping station.

The high standard of municipal practice set by Mr. Stearns in designing and building these Metropolitan Works has had a marked influence on important engineering structures built since in this country. The sound engineering training in investigation, design, and construction, and the object lesson of the merit of careful forethought and study in advance of construction, given by Mr. Stearns to the large number of engineers who constituted his corps and came under his influence, and who after the completion of these works scattered in different directions, to take up active work in other places the country over, where engineering work was under way, has been of far-reaching effect and of the greatest advantage to the public.

In 1900 Mr. Stearns was awarded the gold medal of the Paris Exposition for his exhibit of the Metropolitan Water Supply Works and

for work in the water-supply field. In 1905, Harvard University conferred on him the honorary degree of Master of Arts, and a year later the University of Pennsylvania further honored him with the degree of Doctor of Science.

After the completion and putting into successful operation of the Metropolitan Water Supply Works, Mr. Stearns withdrew from their active management and became the Consulting Engineer of the Board. Eminent as an engineer of wide experience and sound judgment, his advice was much sought. He limited his consulting work, however, to the problems which most interested him. Among the more important projects with which he was actively connected were the water-supply problems of New York City; Baltimore, Md.; Los Angeles, Cal.; Winnipeg, Man., Canada; Hartford, Conn.; Rochester, N. Y.; Providence, R. I.; and Worcester, Mass.; the sewerage problems of Baltimore, Md., Chicago, Ill., Pittsburgh, Pa., and elsewhere; and he was called on to pass judgment on many important dams and structures difficult of execution, built in different parts of the United States and in Mexico.

On June 24th, 1905, the late President Roosevelt appointed Mr. Stearns a member of an International Board to consider and report on plans for a canal across the Isthmus of Panama. The Board consisted of thirteen eminent engineers of whom eight members, constituting a majority, reported a plan for a sea-level canal; while a minority of five, of whom Mr. Stearns was one, reported the plan for the lock canal ultimately adopted by President Roosevelt and by the United States Government as a basis for procedure. Mr. Stearns was probably named on this Board in part for the reason of his experience in building the north dike of the Wachusett Reservoir, which reservoir was considered to be a precedent for the construction of the Bohio or Gatun Dam. Three years later, after construction had begun, the question was raised as to the stability of the Gatun Dam and other matters. President Roosevelt then appointed another Board, of which Mr. Stearns was a member, and it was this Board which accompanied President-elect Taft to the Isthmus and which revised the plans for the Gatun Dam to substantially those used in building it.*

In his work incident to the acquisition of the necessary property and rights in advance of the construction of the Metropolitan Water Supply Works, Mr. Stearns showed good judgment and fairness in dealing with the parties involved. This work carried him into the field of valuation, in which his advice was sought subsequently in a number of important cases, and led a little later to his appointment as Chairman of the Special Committee on Valuation of the Society, appointed to "formulate principles and methods for the valuation of railroad property and other public utilities."

* From information furnished the writer by Allen Hazen, M. Am. Soc. C. E., himself a member of this Board.

His character, thoroughness in detail, and fairness in dealing with difficult situations was further exemplified in the great volume of contract work which he handled without litigation, and the respect which his decisions commanded among contractors as well as engineers.

Mr. Stearns had a keen sense of his obligations to the professional societies, and took an active interest in them. He contributed many valuable papers and discussions to the publications of the Society, covering a wide field of engineering.

His more important papers were the following: "Description of Some Experiments on the Flow of Water, Made during the Construction of Works for Conveying the Water of Sudbury River to Boston";* "Disposal of Sewage in Massachusetts";† "Experiments on the Flow of Water in a 48-Inch Pipe";‡ "On the Current Meter, together with a Reason Why the Maximum Velocity of Water Flowing in Open Channels is below the Surface";‖ "The Development of Water Supplies and Water-Supply Engineering"; Presidential Address at the Annual Convention at Frontenac, Thousand Islands, N. Y., June 26th, 1906.§

He had also contributed significant discussions on other papers before the Society on algæ and the purity of water supplies; changes at the new Croton Dam; decolorization of water; going value of waterworks; hydraulic-fill dams; rainfall, flow of streams, and storage; temperature of lakes; tests of cement; the Bohio Dam; the sewerage system of Milwaukee; the Shone hydro-pneumatic system of sewerage; water power of the Falls of St. Anthony; and the hydraulic jump, in open channel flow at high velocity.

Mr. Stearns was a Past-President of the Boston Society of Civil Engineers, a Fellow of the American Academy of Arts and Sciences, and an Honorary Member of the New England Water Works Association, in the work of which he had been long and deeply interested.

In 1876, he was married to Addie C. Richardson, of Framingham, Mass., who died two years before his death. Two sons, both engineers, survive them, Herbert R. Stearns and Ralph H. Stearns, Assoc. M. Am. Soc. C. E.

Mr. Stearns was intensely human and service was his governing thought. Erect and dignified, he had a simplicity and directness of manner which attracted. Men came to him sure of his friendly interest and sound counsel. Underneath one felt instinctively his force of character, his poise and strength of purpose. As his decisions were the result of thought and careful study of details, he had the ability to

* *Transactions*, Am. Soc. C. E., Vol. XII, p. 1.
† *Transactions*, Am. Soc. C. E., Vol. XVIII, pp. 1, 28.
‡ *Transactions*, Am. Soc. C. E., Vol. XIV, p. 1.

§ *Transactions*, Am. Soc. C. E., Vol. LVI, p. 451.

face strong opposition undismayed, and hold to his point. Thoroughness in the analysis of his problem and deliberate action were fundamental with him, and deservedly gave great weight to his conclusions.

The Rev. Charles E. Park, Pastor of the First Church, in Boston, which Mr. Stearns attended, has characterized him happily in the following words:

"We see him as a true patriot—a lover of his country, of his city—as one whose spirit was a public spirit, and whose time and skill and great ability were joyously employed in the careful, thoughtful, well-considered service of his fellow-citizens, both in State and Nation. * * * Constructiveness, in a spiritual as well as a literal sense, was the keynote of his life; to build up rather than to tear down. * * * He was one of those unto whom much had been given, and from whom much was required. And he met those requirements with generosity and self-forgetting fidelity. * * * It was not peoples' thanks or plaudits that he sought, but peoples' comfort. * * * Their safer, richer, easier living was dear to him."

Mr. Stearns was elected a Member of the American Society of Civil Engineers on October 2d, 1878. He also served as a Director in 1893-95, as Vice-President in 1898-99, and as President in 1906.

JAMES MURRAY AFRICA, M. Am. Soc. C. E.*

DIED SEPTEMBER 18TH, 1918.

James Murray Africa, son of the late J. Simpson Africa and Dorothea Greenland Africa, was born in Huntingdon, Pa., on April 11th, 1863. His father was a well-known surveyor of Huntingdon, who had served a term as Secretary of Internal Affairs of the State of Pennsylvania.

After completing his studies in the public schools of his native town, Mr. Africa entered Juniata College. He was graduated from Rensselaer Polytechnic Institute with high honors in 1888.

Even before his graduation from Rensselaer, Mr. Africa had been engaged in engineering work, having entered, in 1875, an engineer's office as a student. In 1882, he was appointed a member of a commission to determine the lines of Jackson, Miller, and Barree Townships in Huntingdon County, Pa. In 1882 and 1883, he was in charge of topographical and boundary surveys of the coal and ore lands of R. H. Powell and Company, and of the Huntingdon and Broad Top Mountain Railroad, in Huntingdon and Clearfield Counties, Pa. In 1884, he was elected City Engineer of Huntingdon, Pa., which office he retained for nearly thirty years, during which time he designed and constructed the sewerage system of the town, as well as its water-works.

After his graduation, Mr. Africa immediately began to engage actively in his chosen profession as a Civil and Mining Engineer and Geologist. In 1888, he designed water-works systems for Palmyra and Riverton, N. J., and was retained as Consulting Engineer by the Union Trust Company of Philadelphia, Pa., which furnished the funds for the Westmoreland County Water-Works.

In December, 1888, Mr. Africa was appointed Assistant Engineer of the Chautauqua Lake Railroad. He was afterward promoted to be Chief Engineer of that road and, in July, 1889, became also General Manager. From July, 1890, to February, 1891, he was Chief Engineer and General Manager of the Etowah Iron Company, at Cartersville, Ga., for which company he constructed 12 miles of railroad and designed and erected a mill for the concentration of manganese ore. From July to December, 1891, he was in charge of the survey of the lands of the Rockhill Iron and Coal Company, in Huntingdon County, Pa., as well as of the Robert Hare Powell coal operations in Huntingdon, Blair, and Clearfield Counties, Pa.

In 1892 and 1893, Mr. Africa designed and supervised various street improvements in Huntingdon; and, in 1894, he was appointed Chief Engineer of the Pennsylvania Midland Railroad, which position he

* Memoir prepared by the Secretary from information furnished by C. A. Sundstrom, M. Am. Soc. C. E., and on file at the Headquarters of the Society.

held for a number of years. Among his later works were the ganister rock developments of the Harbison-Walker Company, the design and construction of the Standard Steel Works plant, at Burnham, Pa., the recent enlargement of the Pennsylvania Railroad Yards at Northumberland, Pa., and the construction of the Blair Memorial Hospital.

Mr. Africa's one hobby was Masonry. He had become affiliated with that Order at an early age, as a member of Mt. Moriah Lodge of Huntingdon, Pa., and had devoted much of his time and interest to its work. He was also a member of Standing Stone Chapter, No. 201, Royal Arch Masons, and of Huntingdon Commandery No. 65, Knights Templars.

In 1908, he was appointed Consulting and Supervising Engineer of the Masonic Homes Properties, at Elizabethtown, Pa. He superintended the construction of the buildings and laid out the grounds of these properties with the greatest interest and care, giving to the work, because of his great love for its object, the best of which he was capable, having declared that "it was one of the dearest creations of his life."

As a Civil and Mining Engineer, Mr. Africa was widely known throughout the State of Pennsylvania. He was frequently called upon as an expert in lawsuits relative to land surveys and as an appraising engineer in disputed valuations and of property acquired under right of eminent domain. His views as a Consulting Engineer were frequently sought and his opinions were held in high esteem from a legal standpoint.

Mr. Africa was prominently identified with the social, political, and civic life of his community. He was a member of the Engineers Club of Philadelphia, Pa., a Democrat in politics, and a progressive, public-spirited, and useful citizen. In writing of him at the time of his death, the Hon. George B. Orlady, of Huntingdon, states "in private life, Mr. Africa was one of our most important citizens and his untimely death will be mourned by all who ever came within the zone of his influence." In his religious affiliations, he was a consistent member of the Presbyterian Church, and at the time of his death was serving as a Trustee of that church at Huntingdon.

Mr. Africa had been in declining health for several years, suffering from hardening of the arteries and heart trouble. He had, however, kept up his business and professional interests, and for several days prior to his sudden death on September 18th, 1918, at the University Hospital, Philadelphia, Pa., had been engaged in giving expert testimony in an important lawsuit.

On June 1st, 1890, he was married to Miss Eleanor McKnight, of Reading, Pa., who, with three sons, two of whom were in the military service of the United States, during the World War, survives him.

Mr. Africa was elected a Member of the American Society of Civil Engineers, on September 6th, 1896.

HERMON CHARLES ALLEN, M. Am. Soc. C. E.*

DIED MAY 4TH, 1919.

Hermon Charles Allen was born at Coloma, Parke County, Ind., on June 2d, 1870. His primary and high school education was acquired in the county of his birth, and his technical education at Purdue University, where he studied Civil Engineering for three years as a member of the Class of 1894.

In June, 1894, Mr. Allen entered the employ of Cook and Watkins, of Boston, Mass., as Chief Draftsman, which position he retained until January, 1896. From January to June, 1896, he was in charge of the construction of the city water and electric light plant at Gas City, Ind., under the direction of James B. Nelson, a Consulting Engineer of Indianapolis, Ind. After leaving Mr. Nelson, he was engaged from June to November, 1896, as Transitman on the Chicago Division of the Cleveland, Cincinnati, Chicago and St. Louis Railway Company (the "Big Four"), but left this position to accept another with the Illinois Central Railroad Company as Transitman and Assistant Engineer on preliminary surveys, location, and construction.

On the completion of this work, in October, 1897, Mr. Allen entered the employ of the Fort Dodge and Omaha Railroad Company as Resident Engineer on location and construction. He remained with this company until March, 1899, when he returned to the Cleveland, Chicago, Cincinnati, and St. Louis Railway Company, serving from March to July, 1899, as Assistant Engineer on Maintenance of Way, and from July, 1899, to November, 1901, as Supervisor of Track, on the St. Louis Division.

Mr. Allen resigned his position with the "Big Four" to enter the office of the City Engineer of Indianapolis, Ind., as Assistant City Engineer in charge of preliminary and final estimates, street grades, etc. He remained in Indianapolis until September, 1907, when he went West to accept the position of Assistant City Engineer of Great Falls, Mont. In March, 1908, he went to Glasgow, Mont., as City Engineer, where he designed and built the electric light and water systems and made a re-survey of the city, established street grades, etc.

In June, 1909, Mr. Allen returned to Great Falls, Mont., as City Engineer, and remained in that position until 1912, when he removed to Spokane, Wash., where he engaged in private practice as a Consulting Engineer, under the firm name of Tannatt and Allen. This firm handled a number of logging, mining, and irrigation propositions in Washington and Idaho, among which the most important were the irrigation of the Hercules Ranch and the betterments to the Day Brothers Mine, at Wallace, Idaho.

* Memoir prepared by M. L. Morris, Esq., Great Falls, Mont.

Mr. Allen was engaged in the mine work when, in 1918, he was appointed Chief Engineer for the State Highway Commission of Idaho, with headquarters in Boise, which position he held practically up to the time of his death, having just severed his connection with the Commission and entered the employ of Day and Rothrock. He died of heart failure, at Sprague, Wash., on May 4th, 1919, and is survived by his wife.

With his passing, the Profession loses a member of sterling worth and a man with stamina that was unsurpassed.

Mr. Allen was elected a Member of the American Society of Civil Engineers on May 2d, 1911.

WILLIAM ARCHER, M. Am. Soc. C. E.*

DIED NOVEMBER 24TH, 1919.

William Archer was born at Penrith, England, on June 7th, 1844, and came to the United States with his parents in 1850. The Archer family settled at Cleves, Ohio, in the early Fifties, and Mr. Archer made the little suburb of Cincinnati his home for the remainder of his life. After securing his elementary education, he attended Farmers' College at College Hill, Ohio, taking a Liberal Arts Course, but specializing in all the mathematical and scientific courses available.

After spending four years as Assistant Engineer with the "Big Four" Railroad, he entered the service of the West Virginia and Ohio Railroad (now a part of the Baltimore and Ohio) in May, 1869; his active service with the Baltimore and Ohio Railroad System from that date until his death was never severed—a period of more than fifty years. He held positions, successively, as Engineer of Location and Construction, Assistant Engineer, Division Engineer, Principal Assistant Engineer, Maintenance of Way, Assistant Real Estate Agent, and Assistant Engineer in an advisory capacity, which position he held at the time of his death.

Fifty years of continuous active service, beginning with the construction of the railroad west of the Ohio River, gave Mr. Archer an almost unparalleled knowledge of the Western Lines; a wonderful memory, together with an unusual gift for assembling facts in an orderly and concise manner, enabled him to use this knowledge most effectively.

As Assistant Engineer in an advisory capacity, Mr. Archer's knowledge, together with his eagerness to assist all who came to him, made his services invaluable for the securing of historical and statistical data.

Mr. Archer was elected a Member of the American Society of Civil Engineers on March 2d, 1881; he was a Charter Member of the American Railway Engineering Association.

* Memoir prepared from information on file at the Headquarters of the Society.

THOMAS ASPINWALL, M. Am. Soc. C. E.*

DIED MARCH 2D, 1918.

Thomas Aspinwall, the son of William and Arixene Southgate (Porter) Aspinwall, was born in Brookline, Mass., on September 5th, 1853, and died in that town on March 2d, 1918.

He was educated at private schools in Boston, Mass., and at St. Mark's School, in Southboro, Mass., and was graduated with the Class of 1876 at the Massachusetts Institute of Technology.

After a short visit to England and France, Mr. Aspinwall formed a partnership with Mr. Edwin H. Lincoln, opening an office in Boston in February, 1877, under the firm name of Aspinwall and Lincoln, Civil Engineers and Surveyors. This firm is still well known in Boston, and Mr. Aspinwall was associated with it at the time of his death.

On February 3d, 1887, he married Alicia Stuart Towne, of Brookline, and is survived by his wife and two children, Lieut. Thomas Gardener Aspinwall, who served in France during the World War, and Philip Channing Aspinwall.

Mr. Aspinwall's family was one of the most distinguished in the early history of Brookline and Boston. He inherited many of the most excellent qualities of his ancestors, and was at all times a most attractive and delightful companion. He was fond of Nature, and, as a recreation from professional duties, loved to wander through the woods and fields with gun and dog.

Mr. Aspinwall's tastes were also inclined toward military affairs; between 1879 and 1882 he was a member of the First Corps of Cadets, and in 1889-91 he served as Engineer on the staff of Gen. Bridges, with the rank of Captain.

Mr. Aspinwall became a member of the Boston Society of Civil Engineers on March 17th, 1880, and was elected a Member of the American Society of Civil Engineers on May 2d, 1888.

* Memoir prepared by Desmond FitzGerald, Past-President, Am. Soc. C. E.

JOHN ABIEL ATWOOD, M. Am. Soc. C. E.*

DIED FEBRUARY 29TH, 1920.

John Abiel Atwood, the son of John Williams Atwood and Abigail (Doane) Atwood, was born at Chatham, Mass., on February 8th, 1857. He received his college education at New York University, from which he was graduated in 1878 with the degrees of B. S. and C. E.

Shortly after his graduation, Mr. Atwood accepted a position as Transitman with the Third Avenue Elevated Railroad Company of New York City, continuing as such until March, 1879. In 1879 and 1880, he served as Rodman and Leveler with the Elizabeth City and Norfolk Railroad Company (now the Norfolk Southern Railroad), and from 1881 to 1884 as Draftsman with the New York, West Shore, and Buffalo Railroad Company, with headquarters at Syracuse, N. Y.

In 1884, Mr. Atwood returned to New York City and was employed as Assistant to the Chief Engineer of the Tenth Avenue Cable Railway Company until 1886, when he accepted a position as Resident Engineer with the Chautauqua Lake Railroad Company.

From 1887 to 1889, he was engaged as Assistant Engineer with the Lake Shore and Michigan Southern Railroad Company (now part of New York Central Railroad Company).

In January, 1889, Mr. Atwood was appointed Engineer of Construction of the Pittsburgh and Lake Erie Railroad Company, which position he held until May, 1896, when he was made Chief Engineer, continuing in that capacity until his death.

He died at his residence in Beaver, Pa., on February 29th, 1920, after an attack of influenza which later developed into pneumonia with pleurisy complications. He is survived by his widow, one son, and two daughters.

During his tenure of office as Engineer of Construction and Chief Engineer, the Pittsburgh and Lake Erie Railroad grew from a single-track to a four-track railroad, which development necessitated practically the reconstruction of the entire system. Among the first engineering tasks undertaken by Mr. Atwood in his position as Chief Engineer was the relocation of the main line of the railroad, which resulted in a large reduction in grades and a marked improvement in the alignment of the road. The main line was also extended under his leadership, and several branch and tributary lines were constructed, among the latter being the Lake Erie and Eastern Railroad which is located through the heart of the City of Youngstown, Ohio. This line was replete with engineering problems of location and construction.

Large terminal, storage and classification yards, together with round-houses, and locomotive and car repair shops, were designed and built at various places along the road under Mr. Atwood's supervision, as

* Memoir prepared from information furnished by Albert R. Raymer, M. Am. Soc. C. E., and on file at the Headquarters of the Society.

well as passenger stations and station ground layouts along the entire length of the System. In Pittsburgh, Pa., a complete terminal layout was constructed, consisting of a modern Terminal Passenger Station and General Office Building, a Terminal Freight Building, and a large fireproof Storage Warehouse.

All the bridges along the road were also rebuilt, one of the largest being the pin-connected cantilever structure over the Ohio River, at Beaver, Pa., a description of which has been presented before the Society.* On account of the many novel details embodied in its design, this bridge attracted wide attention at the time of its construction, one feature having been the trusses which are protected from damage by derailed equipment by skid girders designed and patented by Mr. Atwood.

"The true engineer is a man of vision and achievement. He derives pleasure from study and design, especially when the problem that confronts him is of an unusual type and demands original treatment. He should temper the ideal with the practical, guarding against waste and extravagance on one hand and narrowness and imperfection on the other. The possession and proper use of these qualities largely define his right to be styled an engineer. The work performed by Mr. Atwood on the Pittsburgh and Lake Erie Railroad during the quarter of a century that he served as its Chief Engineer will bear for many years to come mute testimony to the fact that he possessed in a large degree the qualities above described."

He was in the strictest sense of the term, a Christian gentleman. A man of quiet and retiring disposition, he possessed in a marked degree the ability and willingness to give due consideration to every phase of a controversy brought before him for adjudication. He commanded the highest respect of his superiors and subordinates, to all of whom he was at all times courteous. In speaking of him a few days after his death, one of his friends said that "the crowning work of his life was the development of his own high character and the highest tribute that can be paid him is the simple statement that he was 'John Atwood'".

In religion, Mr. Atwood was a Presbyterian, and had served as an Elder in the First Presbyterian Church at Beaver, Pa. He was a Director and Vice-President of the Beaver Valley Country Club and a member of the Duquesne Club of Pittsburgh, Pa. Among the technical societies to which he belonged were the Engineers' Society of Western Pennsylvania and the American Railway Engineering Association the latter of which he had served as a Director and Second Vice-President and, as Chairman of its Committee on Rails, had performed a most valued service.

Mr. Atwood was elected a Member of the American Society of Civil Engineers on January 3d, 1900.

* *Transactions*, Am. Soc. C. E., Vol. LXXIII (1911), p. 136.

HOLLAND WILLIAMS BAKER, M. Am. Soc. C. E.*

DIED FEBRUARY 18TH, 1919.

Holland Williams Baker, the son of the late Theodore Baker and Margaret Williams Baker, natives of Connecticut and New York State, respectively, was born on September 6th, 1851, at Norwalk, Ohio, where his parents then resided. In his eleventh year, the family moved to Cleveland, Ohio, where his father was engaged in the tannery business, and where the boy attended the public schools, though somewhat irregularly, as ill health during his youth forced him to do most of his studying at home.

Mr. Baker early went into business with a brother in Chicago, Ill., but, after the great fire in that city, he returned to Cleveland where he taught school for about a year. In 1873, he entered Northwestern University as a student in Engineering, but remained only two years; he then transferred to the University of Michigan as a Junior, in the Class of 1877, with which class he was graduated, with the degree of Civil Engineer.

After his graduation in June, 1877, Mr. Baker returned first to Cleveland and then to Chicago, where he remained only until April, 1878, when he was appointed Assistant Engineer under the Missouri River Commission at St. Louis, Mo., where, engaged on the design of snagboats and other river boats, he lived until about 1883, when he went to Tacoma, Wash.

During his residence on the Pacific Coast, he was engaged in a variety of engineering work, including Government surveys, precise levels, etc., on the Columbia River. He returned to St. Louis, in 1889, as Assistant Engineer for the Mississippi River Commission, with which he was engaged until 1891, on river improvement, construction of plant, etc.

During the following ten years, Mr. Baker was in private practice and business. He spent the summer of 1897 abroad, touring the British Isles on a bicycle and going also into France.

In 1901, he went into partnership with B. H. Colby, M. Am. Soc. C. E., a classmate at the University of Michigan, under the firm name of Colby and Baker, Consulting Engineers, but after a short period the partnership was dissolved, and Mr. Baker resumed practice alone.

In July, 1905, he returned to the Government service under the United States Engineer Office, at St. Louis, on the design and construction of two large, steel hull, hydraulic dredges, *Fort Gage* and *Fort Chartres*, and many steel barges and other river plant, and was so employed until November, 1908.

During his several engagements with the United States Engineer Office and the Missouri and Mississippi River Commissions, at St.

* Memoir prepared by William S. Mitchell, M. Am. Soc. C. E.

Louis, Mr. Baker's work in design and construction, both in wood and steel, of snagboats, towboats, dredges, pile-drivers, and river vessels and plant of extremely light draft, added greatly to his reputation as a skillful engineer along such unusual lines, and he became a recognized authority in such matters, his advice therein being much sought. Subsequently, he was engaged, from 1909 to 1912, in similar work for the United States Engineer Office and the Mississippi River Commission, at Vicksburg, Miss., on the hydraulic dredge, *Waterway,* and on barges and a floating steel dry dock. In 1912, he was with the Memphis office (Mississippi River Commission), on the towboats, *Nolte* and *Reese;* from 1912 to 1914, with the Little Rock office, on the hydraulic dredges, *Taber* and *McGregor;* and from 1915 to 1916, at the Duluth office, on the steel hull dipper-dredge, *Gaillard.* It was while engaged on this last vessel, that he was obliged to retire because of his health which had been failing for several years. During the construction of the many vessels on which he was engaged, he resided for various periods at Vicksburg, Miss., Pittsburgh, Pa., Dubuque, Iowa, Green Bay, Wis., etc.

After his retirement, Mr. Baker's health continued to decline and, for the last two years of his life, he was practically confined to the house and his bed. During these latter years, his home was at Columbus, Ohio, where he died. He was buried in Bellefontaine Cemetery, St. Louis, Mo., on February 20th, 1919.

He was married, in Bloomington, Ill., on June 15th, 1898, to Miss Florine Vimont, daughter of the late John M. Vimont, of St. Louis, Mo., who survives him.

In his youth, Mr. Baker became a member of the Baptist Church with which he maintained connection until his removal to Columbus, when, with his wife, he united with the First Congregational Church, under Drs. Patton and Washington Gladden.

Throughout his entire manhood and professional career, Mr. Baker was marked for his high character and poise, and for his great sincerity, directness, and accuracy of thought. He was an excellent mathematician and an able and accomplished engineer, resourceful and accurate, and a most assiduous worker. His kindliness and simplicity, his loyalty to his work and his friends, and his perseverance and dignity, endeared him to all who knew him.

Mr. Baker was elected a Member of the American Society of Civil Engineers on May 7th, 1890. He was also a member of the St. Louis Engineers' Club.

ALONZO CLARENCE BELL, M. Am. Soc. C. E.*

DIED DECEMBER 1ST, 1918.

Alonzo Clarence Bell was born in New Orleans, La., on March 27th, 1859. He was the only son of William H. and Sophie J. Pearson Bell.

His early education was received in the schools of New Orleans, and his professional training was begun under his father, who was one of the best known engineers in Louisiana at that time.

In 1880, Mr. Bell entered the service of the United States Engineer Corps, as Assistant Engineer on river surveys and levee construction. He was in this service for four years; he next spent three years with Morgan's Louisiana and Texas Railroad and Steamship Company (now part of the Southern Pacific Railroad) designing and supervising the construction of buildings and shops. After this, he re-entered the Government service, first on lighthouse construction and, later, in charge of the construction of the Sabine Pass Jetties.

In 1890, Mr. Bell became Assistant Engineer, and, in 1893, Engineer of the Orleans Levee Board, in which positions he had full charge of the construction and maintenance of the levee system of New Orleans. From 1896 to 1900 he was City Engineer of New Orleans. From 1901 to 1907 he was in private practice. In 1907 he became Engineer for the Board of Commissioners for the Port of New Orleans, with which Board he retained connection until his death.

Mr. Bell's long experience with the problems which are peculiar to the Mississippi River rendered his judgment most valuable in all such matters. He was also especially well qualified to deal with the complex and difficult foundation problems of the alluvial basin of the Mississippi River; in addition to which, he was possessed of a broad knowledge and a high order of ability in port development and in many other branches of engineering.

Mr. Bell was a painstaking and thorough student throughout his life, and was at all times fully informed on the progress of his profession.

His extreme modesty and reserve, amounting to diffidence, made him shrink from anything which savored of self-exploitation. His rigid and unswervable integrity, and his dogged tenacity of purpose, won for him the respect of all with whom he came in contact.

He was married on July 18th, 1888, to Miss Nannie Mather, a member of one of the best known families of Louisiana. He contracted influenza in October, 1918, which, with subsequent complications, resulted in his death on December 1st, 1918. His mother and his widow survive him.

Mr. Bell was a Charter Member of the Louisiana Engineering Society and was elected a Member of the American Society of Civil Engineers on March 7th, 1900.

* Memoir prepared by J. F. Coleman, M. Am. Soc. C. E.

AUSTIN LORD BOWMAN, M. Am. Soc. C. E.*

DIED JUNE 3D, 1915.

Austin Lord Bowman, Chief Engineer of the Department of Bridges of New York City, and former Director of this Society, died on June 3d, 1915, after a short illness, in the prime of his vigorous and useful manhood.

He was born on November 14th, 1861, at Manchester, N. H., the second son of the Rev. George Augustus and Ernestine Lord Bowman, and was of Puritan and Pilgrim ancestry on both his father's and mother's side of the family.

He prepared for college at the public High School, Hartford, Conn., and entered Yale in 1879. He was graduated with high honors (Phi Beta Kappa) in 1883, with the degree of B. A.

Mr. Bowman's college course was marked with the same painstaking and conscientious work that characterized his professional career later, and by the determination to master whatever lines of work he undertook. Although it was necessary for him, in order to assist his finances, to engage in tutoring and other lines of student self-help, he, nevertheless, found time to participate in athletics, winning honors in boxing and wrestling. His college education was made possible largely by his own efforts, and his work and success should be an inspiration to any young man struggling for an education and an honorable professional life. In these days, when so much is heard about the study of the humanities as a supplement or foundation for an engineering course, it is interesting to note that Mr. Bowman's college education covered a B. A. degree, without the technical training thought to be so necessary at the present time.

From his work with a country surveyor during his vacations, Mr. Bowman was inclined toward engineering, and on his graduation in 1883, he at once secured a position as Rodman in a locating party for the Hartford and Harlem Railroad, between New Haven, Conn., and New York City. The Railroad Company became financially embarrassed in the late Fall, and Mr. Bowman spent the winter at home. He went to Colorado in 1884. In 1885, he worked for a short time in the office of the City Engineer of St. Paul, Minn., and left this employment to take a position as Transitman in a survey party of the Minnesota and Northwestern Railroad. This work was attended by all the hardships of a hurried railroad survey, through a swampy, heavily wooded, and uninhabited country, and with poor camp outfit.

* Memoir prepared by Albert Carr, J. A. Knighton, and Lewis D. Rights, Members, Am. Soc. C. E.

Mr. Bowman always retained a vivid recollection of the closing days of this survey, when the party subsisted on lard and blueberries.

At the close of this work, he was employed as a Transitman on the location and construction of the Chicago, St. Paul and Kansas City Railroad, and on its completion he came back to the East.

In 1887, after a short engagement on river and harbor work in New Jersey, and another short engagement on the construction of the Kings County Elevated Railroad in Brooklyn, he went to Virginia on the location and construction of the Clinch Valley Division of the Norfolk and Western Railroad. He remained with this railroad until 1890, when his chief became identified with the American Bridge and Iron Company, of Roanoke, Va. Mr. Bowman accompanied his chief as Assistant Engineer and Superintendent of Construction, beginning what, later, became his specialty in his professional life.

From 1890 to 1895, he had charge of the construction of many important bridges and other structures throughout the Southern States, and gained much practical experience which was to prove of great value to him in his later work.

In the fall of 1895 the American Bridge and Iron Company suffered financial trouble, and Mr. Bowman spent the next year in the service of the United States Government. During that period he found time to prepare and submit a competitive design for a bridge over the St. Lawrence River at Quebec, Canada, and secured second place in a world-wide competition.

In 1897, he came to New York City and opened an office as Consulting Engineer, specializing in bridge and structural steel work. He continued in private practice for ten years, and during the greater part of this period, was engaged as Consulting Bridge Engineer for the Central Railroad of New Jersey.

In December, 1907, he was appointed Consulting Engineer to the Department of Bridges of New York City, and in July, 1914, became Chief Engineer of the Department.

During his incumbency as Consulting Engineer, many important matters were submitted to him for investigation and report, notably, the question of the safety and traffic-carrying capacity of the Queensboro Bridge. His report was made the basis of the Department plan for the re-arrangement of the structure to accommodate the traffic of the dual subway system.

Under his direction, the Department carried out very elaborate and important stress-strain measurements, in connection with an investigation of the Williamsburg Bridge, the work being done with the assistance of the Bureau of Standards, S. W. Stratton, Director, at Washington, D. C. On the basis of these investigations, arrangements were made to strengthen the shore span by using an additional

bent and re-boring some of the pin-holes, so as to use larger pins. This delicate operation* was worked out to complete success.

In the report of the Department of Bridges for 1914 and 1915, there appears the following:

"At a meeting of the Commissioner and heads of Divisions of the Department of Bridges of the City of New York held on the fifth day of June, one thousand nine hundred and fifteen, the following resolution was adopted:

"*Whereas,* In the death of Austin Lord Bowman, Chief Engineer, and the technical and engineering head of this Department, we are deprived of an able adviser and a sincere friend and associate, and

"*Whereas,* It is our wish to give expression to our deep sense of loss, and to evince the respect and esteem in which Mr. Bowman was held and our keen appreciation of his lovable personality and high character; therefore be it

"*Resolved,* That all flags be displayed from the bridges of this Department at halfmast on Monday, the seventh of June, and that a copy of this resolution be transmitted to Mr. Bowman's family with the assurance of our profound regret and sincere sympathy."

Mr. Bowman served as Director of the American Society of Civil Engineers from 1905 to 1907; and, from 1909 until his death, he was Chairman of the Special Committee appointed by the Society to consider and report upon Steel Columns and Struts.

The following resolutions were approved by the Column Committee, at a meeting held at Atlantic City, N. J., on June 23d, 1915:

"*Whereas,* it has pleased Almighty Providence to call from his field of earthly labors

Austin Lord Bowman

and,

"*Whereas,* the Column Committee of the American Society of Civil Engineers was honored by his holding the position of Chairman of the Committee from the time of its appointment, and

"*Whereas,* the members of the Column Committee are desirous of expressing their sorrow on account of his loss,

"*Now be it Resolved:* That we, the members of the Column Committee deeply mourn the loss of a sincere friend, a leader among men, an eminent engineer, and a Christian gentleman.

"*Be it further Resolved:* That we desire to record our appreciation of his work in the engineering profession, but more especially on account of his untiring efforts to lead and guide the Column Com-

* *Engineering News*, Vol. 71, May 14th, 1914.

mittee in the solution of one of the great engineering problems of the present generation.

"THE COLUMN COMMITTEE OF THE
AMERICAN SOCIETY OF CIVIL ENGINEERS.

"Committee:

"JAMES H. EDWARDS
CHARLES F. LOWETH
RUDOLPH P. MILLER
RALPH MODJESKI
FRANK C. OSBORN
GEORGE H. PEGRAM
LEWIS D. RIGHTS
GEORGE F. SWAIN
EMIL SWENSSON
J. R. WORCESTER."

Coming at a time when his ability and experience could be of the greatest service to the world, Mr. Bowman's death was a distinct loss to the Engineering Profession.

He was noted for his sympathy and consideration for younger men. No young man coming to him for advice on professional or other problems went away without feeling that he had received more than money could buy.

At the time of his death, Mr. Bowman was a Member of the American Society of Mechanical Engineers, the American Society for Testing Materials, the American Railway Engineering Association, and the Association of Railway Superintendents of Bridges and Buildings. He was also a member of the Yale Club, the Engineers Club, the New York Railroad Club, a charter member of the Massachusetts Society of Mayflower Descendants, a member of the Sons of the American Revolution, and of the Society of Colonial Wars.

In 1883, he was married to Ida, daughter of Garret I. and Mary Jane Van Horne, of Jersey City, N. J., a sister of John G. Van Horne, M. Am. Soc. C. E. His wife died on May 28th, 1905. He again married, in 1907, his second wife being Eleanor, daughter of Matthew and Jane W. Heagen, of New York City, who, with their daughter, Ernestine Jane, survives him.

Mr. Bowman was elected an Associate Member of the American Society of Civil Engineers on September 7th, 1892, and a Member on December 1st, 1897.

OWEN BRAINARD, M. Am. Soc. C. E.*

DIED APRIL 2D, 1919.

Owen Brainard, well known as an architectural and civil engineer, and for many years an associate of the firm of Carrere and Hastings, died suddenly of heart stroke on April 2d, 1919, in New York City.

Owen Brainard was the son of Hubert Brainard and Cynthia Virginia Brainard, and was born on March 10th, 1865. He was descended from the first Brainard who came to the Massachusetts Bay Colony in 1642, and who was among the original proprietors of the Town of Haddam, Conn. His family has been prominent in the affairs of Middlesex County, Connecticut, through several generations, his father, grandfather, and great-grandfather having been members of the Assembly. He received his early education in the local school. Mathematics and history were his favorite studies, and he built on this foundation, by technical reading and hard study in preparation, his professional activities, also receiving instruction from professors of New York University and Stevens Institute of Technology. With an alert, inquiring, and retentive mind, he fitted himself through this study to be one of the leading men of his profession. He had the rare good fortune to choose a field of work which was a source of great satisfaction and interest to him.

Owen Brainard's father was famous in his neighborhood for his skill in masonry building, for his familiarity with mechanical appliances, and his common sense, and as a boy the son learned the practical side of his future work. In his later life, he found this early knowledge of great assistance. In a machine shop in Higganum, Conn., he learned the art of work in metals. From there he went to Philadelphia, Pa., where he lived in Germantown for a number of years.

In 1890 Mr. Brainard returned to Higganum, and there designed and built a church and several houses, one of which was of some distinction. Through these various commissions he was enabled to go abroad for study. On his return he sought New York City as a field in which to practice his profession, and his first effort was in the application of terra cotta to modern steel construction. In 1893, shortly after coming to New York, he secured the position of Engineer with the firm of Carrere and Hastings, and continued in it until his death.

Mr. Brainard's application to his work was practical. He stood for usefulness, endurance, and honesty of structure. He had a keen

* Memoir prepared by Thomas Hastings, Esq., New York City.

interest in and understanding of materials and processes of manufacture, which especially fitted him for the position of architectural engineer.

Through the large and very general practice of Carrere and Hastings, Mr. Brainard was associated with the construction of some of the most notable and important buildings in the United States. He was retained also on the general supervision and structural design of the Cuyahoga County Court House in Cleveland, Ohio, and several large churches in the West.

Mr. Brainard was the Consulting Engineer for the United States Steel Corporation in the development of several of its large towns, and was engaged during the World War in the planning of Camp Meade, and the planning and building of the Workmen's Hotels at Hog Island, Pa., for the Emergency Fleet Corporation. In later years, he had become greatly interested in large sanitation and housing problems, and, at the time of his death, he was looking forward to the study of the needs of the modern city in sanitation and planning.

On his first visit to Europe, Mr. Brainard made a study of lighthouse problems, and he was consulted by the Diamond Shoal Lighthouse Commission when the construction of that lighthouse was projected.

In 1901, Mr. Brainard was made an associate in the firm of Carrere and Hastings, and this connection continued for a number of years, until the larger development of his personal practice. However, his professional connection with the office continued until his death.

He was a member of the Engineers' Club, the Architectural League, the American Institute of Architects, and the City Planning Association. He was also a member of the Century Club, the Apawamis Club of Rye, N. Y., and the Mastigouche Fish and Game Club of Canada.

Mr. Brainard had many charming business and social qualities, and was looked up to and admired by all with whom he came in contact. Those who knew him and consulted him always retained a high regard for his clear-sighted analysis of conditions, his high standard of fair dealing, and his integrity and tactful treatment, whatever the circumstances under which the questions were submitted to him, or whatever the conclusions reached in the problem dealt with. His brevity and conciseness in expressing his conclusions gave judicial character to his technical mastery of his subject.

His recreation was in fishing and golf. He had an excellent sense of humor, and great aptness in the application of a fitting story to the question under discussion. Mr. Brainard gave much of his spare time to reading. He was an earnest worker, never neglecting his

duties, and an active participant in the work of the several professional societies to which he belonged.

On March 10th, 1909, he was married to Jean Sawyer, and made his home in New York City. He had lately built a summer home at Riverside, Conn. Besides his wife, he is survived by two brothers, Daniel and Harrison Brainard, and one sister, Ursula Brainard, who live at the old home in Higganum.

Mr. Brainard was elected a Member of the American Society of Civil Engineers on October 3d, 1906.

FREDERICK BROOKS, M. Am. Soc. C. E.*

DIED JANUARY 10TH, 1919.

Frederick Brooks, the son of Francis A. and and Frances (Butler) Brooks, was born in Boston, Mass., on July 17th, 1848, and died in that city, on January 10th, 1919.

Fred. Brooks, as he preferred to be known, was a graduate of Harvard in the Class of 1868. In college he was distinguished for proficiency in mathematics, a success which naturally led him later to enter the Massachusetts Institute of Technology, where he studied engineering from 1868 to 1870. After leaving the Institute he entered the service of Shedd and Sawyer, at that time a leading firm of Civil Engineers in Boston.

In 1881 Mr. Brooks joined the staff of the Mexican Central Railroad, and for two years was engaged in location on the Tampico Division, where he gained experience in the running of preliminary and location lines, which led to further engagements in similar work for other roads, notably for the Nashua and Lowell Railroad, with which road he remained for three years.

In 1890 Mr. Brooks entered the service of the Boston Water-Works as an Assistant Engineer, and was assigned to the South Framingham office, where he remained for eight years, working on many important problems connected with the maintenance and construction of an extensive system of water supply. When this work ended, he returned to his office in Boston, and resumed his private practice.

Fred. Brooks possessed a keen literary sense which found expression in the writing of professional papers and in the editing of the *Journal* of the Association of Engineering Societies. His papers were for the most part connected with the proposed introduction of the metric system, a project in which he was much interested, but he found time to write on "Mexican Notes," December 19th, 1883, and "Sewage Disposal at Medfield, Mass.," in July, 1888.

The Association of Engineering Societies was a wide-spread movement among the local Engineering Societies for a closer union in connection with the publication of papers. The idea originated with the Cleveland Society in 1881, and it was carried out successfully for many years, until the rapid growth of the local societies rendered it undesirable to continue the joint publication. Mr. Brooks served as editor of the *Journal* from 1905 to 1913. The duties were arduous, but he fulfilled them with ability and fidelity.

His death was accompanied by several tragic features. His health was already somewhat impaired, when he was awakened during the

* Memoir prepared by Desmond FitzGerald, Past-President, Am. Soc. C. E.

night of December 13th, 1918, by the smell of smoke in his room. After a hasty examination he found that the upper story of the house was on fire. On that floor the housekeeper was sleeping. Without thought of self, he seized a fire extinguisher and fought the fire at close range so effectively that he had almost mastered the flames when the firemen appeared and completed the work. Mr. Brooks' head, face, and hands were badly burned, and he was carried to the hospital, where he lingered until January 10th, 1919, and then passed to his long rest.

Fred. Brooks will long be remembered in Boston, where he was for so many years an interesting and prominent member of the engineering fraternity.

Mr. Brooks became a member of the Boston Society of Civil Engineers in 1874, and for the rest of his life was deeply interested in the growth and success of that Society. He was Librarian from 1878 to 1881; Director from 1890 to 1894; Vice-President from 1902 to 1904; and was elected President in 1904.

Mr. Brooks was elected a Junior of the American Society of Civil Engineers on June 7th, 1876, and a Member on January 2d, 1884.

RALPH HENRY BROWN, M. Am. Soc. C. E.*

DIED FEBRUARY 22D, 1919.

Ralph Henry Brown was born at Canfield, Ohio, on August 1st, 1860. He was the son of Richard and Thalia (Newton) Brown. His grandfather was a British officer who fought in the Battle of Waterloo, and was descended from English yeomanry ancestry. Richard Brown was born in England in 1818. He served his apprenticeship as a "draper" in London, and was engaged in business in that city and in Paris. Together with George Williams, a fellow employee, later knighted by Queen Victoria, he organized the first Young Men's Christian Association in the world. He came to the United States when twenty-one years of age, entered the employ of A. T. Stewart and Company and remained with them until about 1853, when he established himself in the dry goods business. While thus engaged, he, with Messrs. William E. Dodge and R. R. McBurney, organized in New York City the first Young Men's Christian Association in this country, and became its first Treasurer. Ralph's mother was born in Ohio, of parents who had moved there from Connecticut as early settlers in that portion of Ohio known as the Northwest Reserve.

Ralph's early education was obtained in the Collegiate School in New York City, the Grammar School at Mount Vernon, N. Y., the High School at Canfield, Ohio, of which he was a member of the first class graduated, and, later, at Wooster University, Wooster, Ohio.

From July to October, 1881, he served as Rodman and Transitman on a short extension of the Painesville and Youngstown Railroad, and for the following year was employed in the office of James M. Reno, City Engineer of Youngstown, Ohio, on city and farm surveying and in coal mine work. In 1883, he established a private practice as a Land and Mine Surveyor at Youngstown, but feeling the need of more specialized education, in the fall of that year he entered the Thayer School of Civil Engineering of Dartmouth University, at Hanover, N. H., and was graduated therefrom in March, 1885.

Immediately after his graduation, Mr. Brown entered the employ of the Boston Bridge Works as Assistant Engineer, and for the next 15 years continued his connection with this company, for 6 years as Assistant Engineer, 3 years as Engineer in Charge of the Estimating Department, and from 1894 as Chief Engineer. During his term as Chief Engineer, the Boston Bridge Works designed and built, among many structures of lesser importance, highway bridges over the Merrimack River at Newburyport, Mass., over the Kennebec

* Memoir prepared by J. R. Worcester, M. Am. Soc. C. E.

River between Fairfield and Benton, Me., over the Back River at Portland, Me., many railroad bridges, and the steel framework of many important buildings, such as armories, industrial plants, storage buildings, and hotels.

In 1900 he associated himself with Mr. A. S. Miller, Jr., in organizing the Eastern Bridge and Structural Company, of Worcester, Mass., and during the remainder of his life devoted himself exclusively to fostering and building up this company. Mr. Brown was a skillful and ingenious designer. Thoroughly grounded in the science of structures, he was intimately acquainted with the practical applications of the art, and able to devise new methods to accomplish his ends. He was always interested in economizing material and labor, and was able to effect many important savings for his clients. Though chiefly concerned with steel construction, he was alive to the uses of other materials. Largely by his ability and untiring industry, the Eastern Bridge and Structural Company has built up an enviable reputation among the users of structural steel in the eastern section of the United States.

Mr. Brown was first married in August, 1889, to Miss Ella Gertrude Gardner, of Brockton, Mass., who died in 1906, leaving a son and a daughter. He was married a second time, to Miss S. F. Palmer, only about two months before his death, which occurred on February 22d, 1919, from a sudden attack of pneumonia.

Mr. Brown was naturally retiring in his disposition and not inclined to enlarge his field of activities beyond his business associations. He was a member of the Engineers' Club of Boston, and the Worcester and the Dartmouth Clubs, of Worcester. During the last ten years of his life he took an active interest in Masonry. He was a Knight Templar and had taken nearly all the Scottish Rites Degrees. He was always a hard and persistent worker, and was just beginning to look forward to a time when he could enjoy more ease. The little time he allowed himself for recreation was spent at his summer cottage in Rutland, Mass., where he took great pleasure in hunting and fishing.

He was greatly beloved by his associates, and had few if any enemies. He had a keen sense of humor, and his hearty, bluff, sincere manner secured him a cordial welcome wherever he went.

Mr. Brown was elected a Member of the American Society of Civil Engineers on June 7th, 1899.

STEPHEN PEARSON BROWN, M. Am. Soc. C. E.*

DIED DECEMBER 6TH, 1919.

Stephen Pearson Brown, the son of Stephen O. and Mary P. Brown, was born at Dover, Me., on April 29th, 1877. After graduation from the Hotchkiss School, Lakeville, Conn., in 1896, he studied a short time in Heidelberg, Germany, and entered the Massachusetts Institute of Technology, from which he was graduated in 1900, with the degree of Bachelor of Science.

Immediately after his graduation Mr. Brown was employed in making tests of lubricating oils under mill conditions for the Washington Mills, Lawrence, Mass. From 1901 to 1903, he was junior partner of the firm of Collier and Brown, Consulting Engineers, Atlanta, Ga., having charge of the mechanical and civil engineering work in hydro-electric developments, sewerage systems, water-works systems, mine developments, and factory and electric plant designs. In 1904, he had charge of the construction of the depot at Bridgeport, Conn., under the Architect for the New York, New Haven and Hudson River Railroad Company, and, in 1905, designed reinforced concrete structures for the Columbian Fireproofing Company of New York City.

On August 1st, 1905, Mr. Brown joined the organization of the United Engineering and Contracting Company of New York City, as Engineer of Construction on the St. Mary's Park Tunnel and the Port Morris depression of the Port Morris Branch of the New York Central Railway. This company late in 1905 sent Mr. Brown to Porto Rico to investigate and report on conditions relating to municipal water-works, water supply, electric light and power from a possible water-power plant, and a sewerage system, all for the City of San Juan, Porto Rico. From 1906 to July, 1908, he had charge of the work of the same company on the Pennsylvania Railroad Company's cross-town tunnels, supervising all work west of Fifth Avenue, New York City.

The last half of 1908 Mr. Brown spent in Europe, investigating foreign practice in hydraulic and tunnel work. He returned to the United Engineering and Contracting Company in January, 1909, as Principal Assistant Engineer, and also acted as Designing Engineer for the Cuban Engineering and Contracting Company, of New York City, up to July of that year, when he returned to Europe for six months' study of tunneling methods. From 1910 to 1912, he was Chief Engineer for the Tidewater Building Company and T. B. Bryson on the Fourth Avenue Subway, New York City.

From 1912 to 1917, Mr. Brown served as Chief Engineer of the Mount Royal Tunnel and Terminal Company, Limited, and Managing

* Memoir prepared from information on file at the Headquarters of the Society.

Engineer for Mackenzie, Mann and Company, Limited, having charge of both design and construction of the terminal development in Montreal, Que., Canada, for the Canadian Northern Railway. This included a double-track tunnel more than 3 miles long, elaborate freight and passenger terminals and an elevated double-track viaduct across the lower town from the tunnel to the harbor. It involved an estimated expenditure of about $15 000 000, and $10 000 000 was actually expended.

From 1918 to June, 1919, Mr. Brown was Vice-President and General Manager of the Ford, Bacon and Davis Corporation, Engineers, and was active in the Construction Department of the International Coal Products Corporation on a Government carbo-coal and by-product plant.

Mr. Brown was a member of the following engineering societies: American Society of Mechanical Engineers, American Railway Engineering Association, Engineering Institute of Canada, and Institution of Civil Engineers (Great Britain). He was also a member of the Engineers Club, and the University Club, both of New York City.

Mr. Brown met his death at Sebec Lake, Maine, when he broke through the ice on which he was crossing to his summer home near Greeley's Landing. He directed his son, whom he had been hauling on a moose-sled, to run to the shore and down to the houses at the landing to give the alarm. The child did so and found two women, but before they could reach him, Mr. Brown had become exhausted and had sunk beneath the ice. As soon as word reached the village a party went to the landing and the body was recovered that night.

He is survived by his wife, who was Miss Edith Luce, of Boston, Mass., and two sons, his mother, and two sisters, Mrs. J. Arnold Norcross, of New Haven, Conn., and Mrs. Clarence F. Dore, of Melrose, Mass.

Mr. Brown was elected an Associate Member of the American Society of Civil Engineers on October 5th, 1904, and a Member on November 1st, 1910.

WILLIAM LYON BROWNE, M. Am. Soc. C. E.*

DIED NOVEMBER 24TH, 1919.

William Lyon Browne, the son of William Lyon Browne and Ellen (Symonds) Browne, was born at Shrewsbury, England, on April 1st, 1876. He obtained his early education at Shrewsbury School, and after a year's study in French and German on the Continent, he spent three years acquiring a business training in mechanical work at Shropshire, England. He studied engineering at The Central Technical College of the City and Guilds of London Institute, under Professor W. C. Unwin, from 1897 to 1900.

In 1900 and 1901, Mr. Browne served under A. Ross, Chief Engineer of the Great Northern Railway (England), on the construction of the Red Bank Viaduct at Doncaster, and during 1901 and 1902, he was engaged on the design of docks and harbor works with Mr. J. J. Eady, and on surveys for tramways, etc.

In 1902, he was employed as Resident Engineer in charge of the Northern Section of the Charing Cross, Euston and Hampstead Tube Railway, in London. He was engaged on this work which consisted of eight miles of tunnel and five stations, from its inception until its completion in 1905, working under Sir Douglas Fox and Partners and W. R. Galbraith.

In August, 1905, Mr. Browne came to Canada, as representative of Sir Douglas Fox and Partners, Engineers-in-Chief of the Atlantic, Quebec, and Western Railway being constructed in the Counties of Bonaventure and Gaspé in the Province of Quebec. He remained in this position until 1907 when, in addition to continuing to act as representative of Sir Douglas Fox and Partners, he was made Chief Engineer in Canada and placed in complete charge of the construction of the Atlantic, Quebec, and Western Railway, 102 miles in length, until its completion in 1911.

Mr. Browne then accepted an appointment as Chief Engineer with the Bishop Construction Company, of Montreal, Que., Canada, which Company held a contract for the construction of part of the Quebec and Saguenay Railway, and, later, was engaged for a time as Resident Engineer for the Armstrong Whitworth Company of Canada.

From 1914 to 1916, he was employed first by the Canadian Inspection Company and, afterward, for the Imperial Government, on shell inspection.

In 1916, Mr. Browne was sent to Greece by the British Manufacturing Agents in charge of a survey for a railway for the Greek Government near Kavala, at which place he died from dysentery on November 24th, 1919.

* Memoir prepared from information supplied by John Nealor, Esq., and on file at the Headquarters of the Society.

Mr. Browne, like many English-born civil engineers, was of a pioneering disposition, as his record shows, and was intensely devoted to his adopted profession. Naturally, his first thought was safeguarding the interests of his principals, yet those who had occasion to meet and deal with him freely admitted his straightforward business integrity at all times. Socially, he was ostensibly a "home" man, devoted to his family. He had a decided preference for the sea coast, and, therefore, it is more than likely that some of the happiest years of his short life were those spent in New Carlisle, Que., Canada, on the borderland of the Gaspé Wilds.

He was extremely interested in art, was fond of open-air sports of every description, and delighted to spend his occasional leisure hours with a rod or gun. Although he had many business acquaintances, his intimate friends in Canada were comparatively few, but those who could claim such privilege deeply mourn the loss of a true, courteous, and generous companion.

Mr. Browne was married in 1903 to Ellen Winifred Nealor who, with two children, survives him.

He was a Member of the Institution of Civil Engineers of Great Britain and of the Canadian Society of Civil Engineers.

Mr. Browne was elected a Member of the American Society of Civil Engineers on January 31st, 1911.

ANDREW BRYSON, M. Am. Soc. C. E.*

DIED OCTOBER 1ST, 1918.

Andrew Bryson, the only son of Rear-Admiral Andrew Bryson and Charlotte Arnold Bryson, was born in New York City, on September 2d, 1851.

After completing his school life, Mr. Bryson began his engineering work in December, 1869, as Rodman on the Connecticut Western Railroad under the late William F. Shunk, Chief Engineer. Mr. Bryson remained on this work until its completion, having been, for the latter part of the time, in charge of a residency.

From December, 1871, to September, 1872, he was engaged on the New York and Long Branch Railroad as Leveler in charge of a locating party, and as Division Engineer preparatory to construction, which, however, was not undertaken at that time. In September and October, 1872, he served as Transitman on the location of the Rhinebeck and Connecticut and the Walkill Valley (extension) Railroads.

After severing his connection with this work, Mr. Bryson went abroad and visited England, Scotland, and France, remaining until July, 1873, when he went to Canada as Leveler on the surveys for the Missisquoi and Black River Valley Railroad, under Mr. Shunk, Chief Engineer.

In April, 1874, he was appointed Division Engineer on the Delaware, Lackawanna and Western Railroad under the late James Archbald, M. Am. Soc. C. E., Chief Engineer. Mr. Bryson retained this position until September, 1878, when he was made Engineer of the Syracuse and Binghamton Railroad, where he remained until August, 1880. During this time, he was appointed Associate Engineer on a project for a proposed bridge across the Niagara River at Lewiston, N. Y., Mr. Bryson representing the American company interested and the late Joseph Hobson, M. Am. Soc. C. E., the Canadian corporation. He also designed and superintended the construction of the docks and coal trestles of the Delaware, Lackawanna and Western Railroad at the foot of Erie Street, Buffalo, N. Y.

From August, 1880, to October, 1882, he served as Division Engineer of the Delaware, Lackawanna and Western Railroad in New York State, and located and superintended the construction of the Third Division, including much heavy work throughout the Genesee Valley.

In October, 1882, he was appointed Chief Engineer of the Hartford and Harlem Railroad and the East River and Connecticut Railroad, which were to form a proposed new line between New York City and New Britain, Conn. After the completion of this work in 1885, Mr.

* Memoir prepared from information on file at the Headquarters of the Society.

Bryson was employed as Principal Assistant Engineer on the Kings County Elevated Railway, Brooklyn, N. Y., until 1887, when he opened an office in New York City and engaged in the private practice of engineering.

In 1900, Mr. Bryson went to Reading, Pa., where he was engaged in the steel industry as President and Treasurer of the Brylgon Steel Casting Company. In 1905, in order to develop his business and to have the advantage of sea transportation facilities, Mr. Bryson moved his plant to New Castle, Del. He continued as its President until 1916, when the plant was sold to the Penn-Seaboard Steel Casting Company.

From that time until his sudden death from Spanish influenza, on October 1st, 1918, Mr. Bryson had devoted himself to community interests. He was intensely patriotic, and had been a leading spirit in the Liberty Loan and Red Cross drives in New Castle, having served as Chairman of the Men's Committee during the Second and Third Liberty Loan drives and had been engaged on plans and arrangements for the Fourth Loan when he was taken ill.

Cultured, educated, and a man of clear and sound judgment, Mr. Bryson's opinions in matters pertaining to his profession and community interests were often sought by others and were always found to be exceedingly helpful and valuable. He was thoroughly democratic in his dealings with his fellow men, demanding from them only his own standards of honesty, uprightness, and patriotism.

Mr. Bryson was a member of the St. Nicholas Club of New York City, the Loyal Legion, and President of the New Castle Branch of the Navy League. He was also a member of the Board of Trustees of the Presbyterian Church at New Castle. In connection with municipal and Federal affairs, he was a member of the New Castle Board of Trade, a commission appointed for the bonding of New Castle for street paving, the Delaware District Board for the consideration of claims and appeals in the matter of exemptions from military service, and of the Board appointed by the Government to collect information concerning the war facilities of manufacturing interests in his district.

Mr. Bryson was elected a Member of the American Society of Civil Engineers on April 1st, 1885.

ROLLA CLINTON CARPENTER, M. Am. Soc. C. E.*

DIED JANUARY 19TH, 1919.

Rolla Clinton Carpenter was born near Orion, Mich., on June 26th, 1852. His father, Charles K. Carpenter, owned an extensive farm at that place, and was the Vice-President of a railroad connecting Detroit and Bay City, which now forms a part of the Michigan Central System.

Rolla Clinton Carpenter's early education was received in the district school and in the Pontiac High School, from which he entered the Michigan Agricultural College, receiving the degree of Bachelor of Science in 1873. In 1875, he received the degree of Civil Engineer from the University of Michigan, and then returned to the Michigan Agricultural College, as an Instructor and Graduate Student, receiving the degree of Master of Science in 1876. In 1878 he was elected Professor of Mathematics and Civil Engineering at the same institution, and served in this position until 1890.

As his vacations occurred during the winter, Professor Carpenter spent a part of the time in study at other engineering colleges. At the Massachusetts Institute of Technology he studied under Professors Peabody and Lanza. His graduate study was completed at Cornell University, which conferred on him the degree of Master of Mechanical Engineering in 1888. His relation as Consulting Engineer to the Lansing Iron and Engine Company, of Lansing, Mich., placed at his disposal the facilities of a large and up-to-date manufacturing plant, which afforded opportunities for investigation exceeding those of any technical school. He was thus greatly assisted in the preparation of his thesis on the subject of "Internal Friction in Non-Condensing Engines." The late Robert H. Thurston, M. Am. Soc. C. E., then Dean of Sibley College, read a paper on this thesis before the American Society of Mechanical Engineers, and, in his discussion, showed that Professor Carpenter's investigations played an important part in changing ideas then prevalent about steam engine friction.

In 1890, Professor Carpenter was called to Cornell University by his election as Associate Professor of Mechanical Engineering in Sibley College. The mechanical laboratory work was then organized as a separate department under his direction, and, during the next five years, the equipment of the laboratories was rapidly enlarged. Professor Carpenter's intimate relation with various industrial enterprises peculiarly fitted him for the development of a course of instruction in Experimental Engineering. His success in this respect had a pronounced influence on similar courses in other engineering colleges, and on the methods of teaching other sciences. In 1895 he was promoted to a full professorship, and his title was changed to that of

* Memoir prepared by Henry S. Jacoby, Assoc. Am. Soc. C. E.

Professor of Experimental Engineering. This position he held until the time of his retirement from active service, in June, 1917.

Professor Carpenter's "Notes on Mechanical Laboratory Practice" was published in 1891. This work formed the basis of his later book on "Experimental Engineering", which has been the leading manual on the subject in the United States. The first edition of his book on heating and ventilation, entitled "Heating and Ventilating Buildings", was published in 1895. This book has had six revisions and an extensive circulation. It contains much original material from the author's own experience, and is quoted largely by later writers on the subject. He was a joint author with Professor Diederichs of a text-book on "Gas Engines." He also made numerous contributions to engineering periodicals and to the transactions of various societies, notably the American Society of Mechanical Engineers, the American Society of Civil Engineers, and the American Society of Heating and Ventilating Engineers. He was a frequent contributor to *The Sibley Journal*, of which college periodical he was an Associate Editor during the entire period of his official relation to Cornell University.

He was engaged in a diversified field of investigation and research, which included problems relating to power plants, gas engines, cement manufacture, coke manufacture, railway management, heating and ventilating, etc. He was one of the greatest patent experts in the country, and was employed by many of the leading law firms in various parts of the United States. He invented a number of pieces of laboratory apparatus, such as the Carpenter coal calorimeter, which was for many years a standard for testing the heating value of coal; the throttling and separating steam calorimeters, extensively used at present; a friction testing machine, which may be found in most of the large laboratories; and an inertia governor for the steam engine.

Professor Carpenter had been honored by appointment to various positions of distinction and trust. He was a judge of machinery and transportation at the Columbian Exposition at Chicago in 1893, at the Pan-American Exposition at Buffalo in 1901, and at the Jamestown Exposition in 1907. He was a member of the commission appointed by the Academy of Science in 1915, at the request of the President of the United States, to investigate the slides at the Panama Canal and to make such recommendations as in the judgment of the commission would improve the conditions and lessen the possibilities of slides in the future. In 1907, the Michigan Agricultural College conferred on him the degree of Doctor of Laws.

He was a member of eight of the leading engineering societies of America; during 1908-11, he was Vice-President of the American Society of Mechanical Engineers, and had served on various committees, the most important service perhaps being rendered on the Boiler Code Committee. He was President of the American Society of

Heating and Ventilating Engineers in 1898, Vice-President of the American Society of Automobile Engineers in 1910-12, and he had taken an active interest in the student branch of the American Society of Mechanical Engineers at Cornell. He was a member of Tau Beta Pi, and Sigma Xi, being President of the Alpha Chapter of the latter society in 1912-13. His relation to social and fraternal societies included membership in the Engineers' Club of New York City, the New York Railroad Club, the Town and Gown Club of Ithaca, Delta Tau Delta, and the Masonic fraternity.

Professor Carpenter's kindly manner and genial disposition made it easy for even the most timid to approach him, and he was never too busy to be considerate of any one who sought his counsel and advice. His enthusiasm in original investigation, and his capacity for hard work inspired his students to a similar attitude and effort. Outside the University his counsel was widely sought by the Government, in large engineering undertakings, and in patent legislation. His colleagues in the faculty appreciated his good judgment and his extensive knowledge of the engineering profession and of human nature. He was a pleasant companion and a loyal friend. Thus, his influence has been far-reaching both in engineering education and practice.

At the beginning of November, 1918, Professor Carpenter fell and fractured his leg, and this confined him to his home. Before this, he had made his contribution to war work by devoting himself untiringly to the development of the Liberty motor. This obliged him to travel extensively, and that is believed to have aggravated a spinal ailment due to a fall about three years before. He died on January 19th, 1919.

He was married to Miss Marion Dewey, at Greenville, Mich., on May 25th, 1876. His wife, two sons, and a daughter survive him.

Professor Carpenter was elected a Member of the American Society of Civil Engineers on April 4th, 1911.

CHARLES TITUS CHURCH, M. Am. Soc. C. E.*

DIED AUGUST 25TH, 1919.

Charles Titus Church, the son of the Rev. Samuel Clemon Church, D. D., and grandson of Capt. Samuel Church, the pioneer founder for whom Churchville was named, was born at Churchville, N. Y., on October 6th, 1834. His mother, Mary Hall (Bangs) Church, was also of early New England ancestry—a great-great-great-great granddaughter of Edward Bangs, the Pilgrim, who came from England in the *Anne* in 1623. She came from Massachusetts to make her home in Western New York in 1822.

While Dr. Samuel C. Church was pastor of the Methodist Episcopal Church, in Medina, N. Y., his son, Charles, received his academic education at the Medina Academy. He then entered Union College, from which he was graduated, with the Class of 1856, with the title of Graduate in Civil Engineering and the degree of Bachelor of Arts.

In March, 1857, Mr. Church went to Iowa and served as Rodman on the preliminary surveys for a railroad from Dubuque to Anamosa. In June, he became interested in the proposed improvements for using the water power on the Illinois side of Rock Island, but after he had designed the masonry dams, etc., the plans for this enterprise were abandoned.

In 1859, Mr. Church became a teacher in charge of a graded school at Port Byron, Ill., and, from 1861 to August, 1862, he was Superintendent of the public schools of Rock Island, Ill. From August, 1862, to July, 1864, he was engaged "in land operations" with an office at Moline, Ill.

In July, 1864, he went to Colorado in the employ of a gold mining corporation, and made topographic surveys of the mountain passes at the head-waters of the Arkansas, South Platte, and Blue Rivers and reaching over the Great Divide to the Pacific Slope. A portion of this survey was afterward used by the Pacific Railway's explorers. Mr. Church then returned to Illinois where he remained during October and November, going East in December to New York City to complete the maps of the survey, which were turned over to the Copalinshe Mining Company.

In July, 1866, he was employed as Mining Superintendent by the Champion Silver Mining Company and, in its interests, went, *via* the Isthmus of Panama, to San Francisco, Cal., and thence to Silver Peak, Nev. He made a thorough examination and a report of the Company's property at Silver Peak, but the owners decided to defer mining operations, and Mr. Church returned to New York City.

* Memoir prepared from information on file at the Headquarters of the Society.

From 1867 to 1869, he served as Agent for the American Tunnel Machine Company, directing the operation of the draftsmen and model maker. In the meantime, in November, 1868, he returned to railroad work, as Transitman on a preliminary survey for the Lake Shore Railroad from Middletown to Willimantic, Conn.

In March, 1869, he was appointed as Transitman on preliminary surveys for the New York, Ontario, and Western Railroad in Delaware and Sullivan Counties, New York State. In September of that year, he was made Assistant Engineer on Construction of the same road, which position he held for three years until the track was laid and the work completed.

In 1873, Mr. Church was engaged with the Central Railway Construction Company, of New York City, as Draftsman and Office Engineer, and from January, 1874, to May, 1875, he served as Clerk in the "eastbound" office of the Erie Railroad Company at Long Dock, Jersey City, N. J.

In May, 1875, he was appointed Assistant Engineer on the Lake Ontario Shore Railroad, in charge of construction through Oswego, N. Y. This work consisted of carrying a railroad bridge across the Oswego River and out to the new harbor.

In 1876 and 1877, Mr. Church was engaged in farming in Michigan and teaching school in Monroe County, New York State. In November, 1877, however, he went to Boston, Mass., as Office Engineer, Draftsman, etc., for Col. T. H. Dupuy, Consulting Engineer for the Boston, Hoosac Tunnel, and Western Railroad Company, which position he retained until 1880.

From August, 1880, to the fall of 1881, he was engaged on the location and construction of the Saratoga Lake Railway as Assistant Engineer and Acting Chief Engineer, respectively, and, from that time, until October, 1882, he served as Chief Engineer of the Boston Hoosac Tunnel Railroad.

From 1882 to 1886, Mr. Church was employed as Chief Engineer on the surveys, betterments, etc., for the Lebanon Springs Railroad, leaving this position to engage on location surveys for the Housatonic and Northern Railroad from the State Line, on the Boston and Albany Railroad, to Bennington and North Bennington, Vt.

In 1887, he served as Chief Engineer on the location and construction of a railroad from Derby to Botsford, Conn., in the interest of the Housatonic Railroad Company, and, in 1888 and 1889, he was engaged in the private practice of engineering, with an office at Saratoga Springs, N. Y.

From March to July, 1890, Mr. Church was employed as Assistant Engineer by the Lehigh Valley Railway Company on construction covering the crossings of the Genesee River and Oatka Creek, and from October, 1890, to October, 1892, he served as Civil Engineer for

the Retsof Mining Company on mine surveys, mapping, and railroad construction connecting the mine with the Delaware, Lackawanna, and Western Railroad, as well as with several other railroads near Caledonia, N. Y.

From October, 1892, to July, 1895, Mr. Church was employed as General Freight and Passenger Agent of the Genesee and Wyoming Valley Railroad Company, and from that time until 1899, he was engaged in private practice, surveying, mapping lands, etc.

In the meantime, his family had become residents of Geneva, N. Y., and, in 1899, Mr. Church became identified with the municipal government of that city, serving for two years as City Engineer and afterward as City Engineer and Superintendent of Public Works until 1912, when he resigned and retired from active work. He continued his residence in Geneva where he died on August 25th, 1919. He is survived by a nephew and several nieces.

Mr. Church was married, in New York City, on August 26th, 1873, to Miss Frances Ann Van Zandt, daughter of Beekman and Frances Susanna (Van Buren) Van Zandt. Mrs. Church died on October 14th, 1910.

Mr. Church was thorough and accurate in all his work and undertakings, as thorough in his reading as in other things, a reader of many books, papers, and magazines, and interested in events of the day to the very last. Hospitable, gallant, suave—something of the type of the "old-school gentleman"—with an excellent memory, keen wit, and remarkably lucid expression of his thoughts or opinions, Mr. Church was a delightfully entertaining host; but he did not care to visit his club or other places where men usually gather; he liked the quiet of his home. He was a member of the University Club, the Elks, and the Masons, but never held office in any of them. He was a Vestryman of Trinity Protestant Episcopal Church, in Geneva, N. Y., from 1894 to 1917, and for some years served as Clerk of the Vestry.

Mr. Church was elected a Member of the American Society of Civil Engineers on May 1st, 1889.

HOWARD LINCOLN COBURN, M. Am. Soc. C. E.*

DIED JUNE 18TH, 1918.

Howard Lincoln Coburn was born on January 13th, 1867, at Patten, Me., the son of America Thayer Coburn, a merchant of that town, and Annabelle (Tine) Coburn, of Lee, Me. He attended the schools of Patten and entered the Massachusetts Institute of Technology in 1883 as a member of the Class of '87.

When he had completed two years of his course in Mechanical Engineering his father met with reverses in business and Mr. Coburn promptly withdrew from college and went to work. He entered the office of Mr. Charles Carr, a mill engineer, of Boston, Mass., with whom he spent most of his time during the ensuing ten years, designing buildings and equipment for New England cotton mills.

After ten years in business, Mr. Coburn re-entered the Massachusetts Institute of Technology in 1896, and was graduated in 1898 with the degree of S. B.

Again taking up mill construction, he spent two years in the office of the late E. D. Leavitt, M. Am. Soc. C. E., of Boston, and then became connected with the firm of Lockwood, Greene and Company, with which he spent ten years, and rose to be Chief Engineer.

In 1905 he began the work which has made his name most familiar to the Engineering Profession, and to it he continued to devote his talents up to the time of his death. He joined the newly organized Ambursen Hydraulic Construction Company, as Chief Engineer. In the following years, he was responsible for the construction of more than one hundred reinforced concrete dams and hydro-electric developments. His work covered nearly every State in the Union, and included many installations in Canada and the West Indies. Some of his biggest and best known works are the Guayabal Dam, for the Porto Rico Irrigation Service, the Bassano Development, for the Canadian Pacific Railway, in Alberta, Canada, the Ozark Dam on the White River, in Missouri, and the La Prele and Shoshone Dams, in Wyoming.

Mr. Coburn made studies of nearly every important river in the United States. At different times he acted as Consulting Engineer to H. L. Doherty and Company, H. M. Byllesby and Company, and other prominent banking houses.

He was a man of unusually attractive personality and had a host of friends, all of whom knew him and loved him as "Pa" Coburn. He was a man to whom other men—especially young men—instinctively went for advice and help, and they always got what they needed. His habit was to be perfectly frank at all times on every subject, but his sympathy and generosity were never failing.

* Memoir prepared by Spencer W. Stewart, Assoc. M. Am. Soc. C. E.

In all his relations, professional and personal, Mr. Coburn's predominant characteristic was absolute sincerity. There was not a square inch of veneer on him, and there was never a doubt of where he stood on any subject. His professional opinions were bluntly stated, and were not subject to review for any consideration, commercial or otherwise.

Mr. Coburn was never married. He is survived by three sisters, Mrs. A. W. Sampson of Rochester, N. Y., Mrs. Charles A. Byram of Patten, Me., and a third who lives in California.

He was a member of the American Society of Mechanical Engineers, and of the Engineers and Technology Clubs of New York City, and the Engineers Club of Boston. He was a life member of Aberdour Lodge, A. F. and A. M., and Aleppo Temple, both of Boston.

Mr. Coburn was elected a Member of the American Society of Civil Engineers on March 5th, 1912.

WILLIAM WATSON COE, M. Am. Soc. C. E.*

DIED MARCH 31ST, 1920.

William Watson Coe was born in Bethlehem, Conn., on November 19th, 1846. He began his studies preparatory to entering the Engineering Profession when he was about fifteen years old. He first made Charles Town, W. Va., his home in 1872, having gone there in connection with the first projection of the Shenandoah Valley Railroad.

Mr. Coe began his professional career in 1866-67, when he held the position of Rodman to Topographer on the surveys for the Dutchess and Columbia Railroad. From 1868 to 1871 he was, first, Rodman and, later, Resident Engineer on the construction of the Dutchess and Columbia Railroad, and in that period was also Assistant and Resident Engineer on surveys and construction of the Connecticut Western Railroad. During the two years from 1872 to 1874 he was Engineer in Charge of surveys for the Plymouth, Kankakee and Pacific Railroad and the New York and Long Branch Railroad; Engineering Assistant to the contractor for the Mobile and Northwestern Railroad; Principal Assistant Engineer on the survey for a branch line of the Atlantic and Great Western Railroad, and Engineer in Charge of the survey of the Carrolton Branch of the New York, Lake Erie and Western Railroad. From 1875 to 1877, he was Superintendent of a division of the Centennial Exhibition at Philadelphia, Pa.

During 1877-78 Mr. Coe served as Principal Assistant Engineer to the general contractor who built the Pittsburgh and Lake Erie Railroad. In 1879 he was made Principal Assistant Engineer of the Shenandoah Valley Railroad, and during the same year became its Chief Engineer, which position he held until 1885. He was appointed Chief Engineer of the Norfolk and Western Railroad in 1881, a position which he continued to hold with that company until 1897. During this period the Norfolk and Western Railroad was increased in mileage by the construction of about 500 miles of new line through the mountainous country in Virginia and West Virginia, reaching the iron and zinc ore territory of Virginia and the Pocahontas coal lands of Virginia and West Virginia. From May, 1897, until February, 1904, Mr. Coe was Engineer of Branch Line Construction of the Norfolk and Western Railway Company.

On February 1st, 1904, he became General Manager of the Pocahontas Coal and Coke Company, having charge of all its coal lands, including about 300 000 acres, with offices at Roanoke, Va. Thereafter, he was continuously engaged in the extension of these holdings, the perfection of titles, and the development of the coal lands.

* Memoir prepared by Charles S. Churchill, M. Am. Soc. C. E.

During his professional life since 1880 Mr. Coe was especially interested in the upbuilding of the southwestern district of the State of Virginia, and considerable areas of coal lands in West Virginia. He was always interested not only in the improvement of the country, but in the welfare of the people in those parts of Virginia and West Virginia, where a large increase in population has taken place since 1881. He was actively engaged in business until a short time before his death, which occurred at his home in Charles Town, W. Va., on March 31st, 1920, as the result of a stroke of paralysis suffered about two months previously. He was buried in Edge Hill Cemetery, Charles Town, on Friday, April 2d, 1920.

Mr. Coe was married in 1880 to Miss Sallie R. Travers, the daughter of the late William H. Travers, of Charles Town, W. Va., who, with a son and a daughter, survives him.

He was a talented engineer and a very capable business man, and was highly regarded by every one with whom he had dealings.

Mr. Coe was elected a Member of the American Society of Civil Engineers on April 3d, 1889.

CLARENCE COLEMAN, M. Am. Soc. C. E.*

DIED OCTOBER 23D, 1918.

Clarence Coleman, son of the late Clayton Glanville Coleman and Sarah Macon Jerdone Coleman, was born at Jerdone Castle, Louisa County, Va., on April 4th, 1849. His father was General of the United States Militia, before the Civil War.

Mr. Coleman was tutored at his home, as a boy, attended several private schools in his State, and then studied at the Virginia Military Institute and at Washington and Lee University, Lexington, Va.

When he was a very young man he was employed for several years (1870-72) by the Houston and Texas Central Railway in various capacities, from Rodman to Resident Engineer, on the location and construction of 200 miles of that road. Then, for 2½ years, he was engaged in private practice at Dallas, Tex. In 1875 he was Engineer of a geological survey for the Buffalo, Bayou and Colorado Railroad, and during the following five years was engaged in private engineering practice at Richmond and Kenmuir, Va. He served in 1881 as Assistant Treasurer of the Richmond Street Railway Company, and in the latter part of that year and in 1882 as Instrumentman on the Chesapeake and Ohio Railway.

He was Engineer of the Arminius Copper Mines Company, and the Sulphur Mines Company, both of Virginia, from 1883 to 1885, during which time he made surveys and installed a complete mining plant for the first named company, and built two branch railways from the mines to the main line of the Chesapeake and Ohio Railway. From May, 1888, until the end of that year, he was in charge of the construction of the terminal docks and transfer bridges of the Housatonic Railroad Company at Wilson's Point, Conn., and, in the same year, made an inspection and report on the company's bridges in Massachusetts.

For a little more than a year, in 1889-90, Mr. Coleman was Chief Engineer of the Santa Fé Southern Railway, and located 48 miles of mountain road over the Ortiz Range.

After a year's private practice as Consulting Engineer at Roanoke, Va., in 1890-91, he entered that city's service, first for four months as Building Inspector, then, for two years (February, 1892, to March, 1894), he was Engineer Member of the Board of Public Works, during which time a sewerage system was planned and built, and pavements and bridges were constructed. While in Roanoke he was a member of the Association of Engineers of Virginia, and in 1892 was elected President of that Association. Two of his contributions to the Association bore the following titles: "The Engineer as a Factor in the Development of Virginia" and "What our Bad Roads Cost Us."

* Memoir prepared by John H. Darling, M. Am. Soc. C. E.

The foregoing record gives an outline of Mr. Coleman's work during the first period of his professional career as a civil engineer, which it is seen consisted mainly of railroad construction and municipal improvements, with intervals of private practice, all of which work was within the Southern States. His activities were now transferred to the northern part of the country, in the Duluth District, where he was engaged during the remainder of his life on Government harbor improvements, carried on by the War Department, with officers of the Corps of Engineers in charge of the District. He was appointed Assistant Engineer by Maj. Clinton B. Sears on November 27th, 1894, and continued to act in that capacity until November 23d, 1917, when he was made District Engineer. He held the latter position until removed by death.

Mr. Coleman's work in this district consisted mainly of marine concrete construction, in which he specialized. First, at Marquette, Mich., Harbor from 1894 to 1898, inclusive, he commenced the construction of a concrete superstructure to the old timber-and-stone breakwater, in accordance with a general design prepared by Maj. Sears, the officer in charge. In this construction the old timber with its rock filling was removed down to about 2 ft. below the water line. Concrete footing blocks, moulded ashore, were laid along the two edges of the timber cribs, and, between and above these, mass concrete was deposited in forms. A gallery traversed the entire length. After a considerable portion had been built, Mr. Coleman was transferred to Duluth, and the work was completed by other engineers.

At Duluth-Superior Harbor, in 1898-1902, he was in charge of the construction of the concrete superstructure for the new combined timber and concrete piers, or jetties, which define the entrance channel from Lake Superior to the north end of Duluth-Superior Harbor. In this case, as at Marquette, there were concrete footing blocks surmounted by monoliths of mass concrete. At the lakeward ends substantial pierheads were built for supporting light stations.

At the south, or Wisconsin, entrance to Duluth-Superior Harbor, also known as Superior Entry, Mr. Coleman, in 1903-09, built some all-concrete revetment piers, which were designed by himself, under the direction of Maj. D. D. Gaillard, Corps of Engineers, U. S. A. The main purpose of these piers was to serve as revetments at the two sides of the entrance channel for retaining the sand of the spit through which the entrance passed. In this construction, which is a departure from the usual types, there are monolithic sections or units, 16 ft. in length, moulded *in situ* around and on foundation piles sawed off a short distance above the level of the bottom, which had been dredged to a depth of 21 ft. below low water. Specially designed removable forms and machinery for handling them were part of the rather expensive plant required for this work.

The construction of these revetment piers was the most original work accomplished by Mr. Coleman, and possibly the most important, also, when its value is considered as an example for similar constructions where conditions are favorable. It has been described in several technical publications.

Among other constructions in the Duluth District, in charge of Mr. Coleman under direction of officers of the Corps of Engineers, may be mentioned the following:

The project of a Board of U. S. Engineers for the further improvement of Superior Entry, approved April 5th, 1907, under which was built, in 1907 to 1912, two converging breakwaters, comprising 4 205 lin. ft. of rubble mould, 900 ft. of stone-filled cribs with concrete superstructure for pierheads, and 896 ft. of concrete shore revetments; the dredging of a stilling basin within the breakwaters with an area of 35 acres (completed in 1915), and the dredging of a harbor basin of 98 acres (completed in 1914); the completion of a 1 500-ft. rubble mound extension to the Marquette Breakwater, in 1914-18.

Mr. Coleman was assigned to the charge of the Duluth District on November 23d, 1917, with the title of District Engineer, following the transfer to another post of Col. D. W. Lockwood, the officer in charge. He held this position until his death in the following year.

Mr. Coleman served in the capacity of Consulting Engineer on a number of private and corporation projects. Owing to his research and experience, he was considered an authority on concrete, and was often called in consultation on this subject.

He was married in 1873 to Miss Bena Randolph Philips, daughter of John Penn Philips, a prominent lawyer of Warrenton, Va., and Elizabeth Lewis Pickett Philips, who was a cousin of Gen. George Pickett, of Gettysburg fame. No children survive. Their union was a happy one, and their home was warm with true southern hospitality. Mr. Coleman was a good liver, and a cheerful disposition beamed from his face. His memory was stocked with a choice assortment of anecdotes and humorous stories, many of them in the negro dialect, which often aptly enlivened his conversation and spiced his public addresses.

He was fond of music, and played the violin in his home. He was a connoisseur of this instrument, and had a hobby for looking up and possessing a collection of old historic violins of rare quality and value which he took pleasure in describing to his friends. In religion, Mr. Coleman was a Roman Catholic, and he and his wife were faithful members of that church.

His final illness extended over a period of four months. Its nature seems not to have been well understood, but hardening of the arteries was said to be the ailment. During the earlier part of his illness he made brief visits to the office, and when unable to leave home he con-

tinued to transact necessary official business at his house. Thus, he "died in harness", at the age of 69.

Mr. Coleman was elected a Member of the American Society of Civil Engineers on November 3d, 1897. At the time of his death he was First Vice-President of the Duluth Association of Members of the American Society of Civil Engineers.

WILLIAM WILLIAMS CREHORE, M. Am. Soc. C. E.*

DIED SEPTEMBER 13TH, 1918.

William Williams Crehore, the son of John T. Crehore and Lucy Williams Crehore, of Cleveland, Ohio, was born in that city on February 3d, 1864.

Those who knew Mr. Crehore intimately held him in high esteem for his great ability in his profession and for the loftiness of his ideals and purity of character. In this he resembled his father, a distinguished civil engineer and a mathematician of high rank, who died on October 7th, 1884.

Mr. Crehore was graduated from Yale University in 1886, having been obliged to lose a year owing to a railroad accident resulting in a broken leg. After 1886, he tutored for a year; he was then given the Larned Scholarship, and returned to Sheffield (Yale) Scientific School for the post-graduate course in Engineering. He took his degree of Civil Engineer in 1888. During the same year he was married to Anna, the eldest daughter of the late Frank W. Ballard, of New York City. He was then for two years Principal of the Hemenway High School, in Norfolk, Va.

In 1889 Mr. Crehore acted as Bridge Inspector for the Pennsylvania Railroad, at Lewistown, Pa., where the Johnstown Flood had made necessary the rebuilding of several bridges. In 1890 he entered the service of Cofrode and Saylor, Bridge Builders, in Pottstown, Pa.; later, he worked for the Baltimore and Ohio Railroad and for the Wallis Iron Works, of Jersey City, N. J., before he opened an office in 1892 in New York City as an independent Civil Engineer.

At just about that time there came into vogue the system of steel frame construction for tall buildings, and Mr. Crehore was one of the first to develop structural designing in that branch of engineering. His resourcefulness and skill as an engineer was shown by the fact that he was called on as a consultant for many large buildings in New York City, in the West, in Cuba, and in the South. The cantilever foundations of the tall American Tract Society Building in New York City were originated and designed by him especially to suit that difficult foundation case. He also developed special designs for foundations under buildings to prevent the menace from quicksand to surrounding structures.

Mr. Crehore, as a public spirited citizen, took a great interest in the advocacy and discussions of the subways in New York City, acting as an adviser to the Merchants Association of New York and also in the public controversies which arose as to the economy and safety of some of the bridges across the East River. He also gave his time and

* Memoir prepared by Gustav Lindenthal, M. Am. Soc. C. E.

services generously to public welfare in his home town, Metuchen, N. J., where he lived before going to California. He was a most intense and enthusiastic worker in anything to which he put his hand, and those who dealt with him had complete confidence in his judgment and thoroughness.

He had a profound love of truth and a loathing for all false assumption. He hated sham, humbug, and charlatanism with all the energy of his soul, and these traits made for him a host of staunch friends.

Mr. Crehore's many-sided nature is shown by the fact that he was an assiduous student of economics and had written a scholarly work, "Protection's Brood", dealing with the problems and economic evils arising from the protective tariff, and particularly pointing out the corruption bred by the excesses of that system. The book gives evidence, not only of painstaking research and analysis, but also, in its easy fluent style, of high literary ability. His discussion is a model of fairness, clarity, and comprehensiveness, and his emphatic language and unsparing criticism of certain evil conditions that had resulted from ruthless competition contributed not a little to their correction, and earned for him a high reputation among thinkers and students of economics. Mr. Crehore properly considered National economics a legitimate field for the study and activity of the Engineer, whose professional interest should be centered through them in the development of public utilities and great public works.

During his college days, Mr. Crehore had obtained a fine musical education from New York's best teachers, and he was passionately fond of classical music. With his fine baritone voice he was a valuable member of the University Glee Club of New York from its organization, in the early Nineties, and sang regularly with it until he left—a sick man—for the West in 1915.

Mr. Crehore was very devoted to his family. He left a widow and nine children—four sons and five daughters. Three of his sons distinguished themselves during the World War, in France, in the military service of the United States. One son, Sergeant Austen B. Crehore, volunteered in the French Lafayette Flying Corps, and received for his valor the Croix de Guerre with palm.

Mr. Crehore's long illness prepared his friends for his death, and this he faced with cheerful resignation. With members of his family around him, he passed through days of happiness, in spite of his fatal affliction. He died at Los Angeles, Cal., on September 13th, 1918.

His many lovable qualities, his rectitude, and his fine character will not be forgotten by those who had the privilege of knowing him intimately, and they, with his family, cherish his memory as that of a noble and manly nature.

Mr. Crehore was elected an Associate Member of the American Society of Civil Engineers on April 4th, 1894, and a Member on September 3d, 1902.

JOSEPH BAKER DAVIS, M. Am. Soc. C. E.*

DIED MARCH 9TH, 1920.

Joseph Baker Davis, the son of Ebenezer Hathaway and Mehitabel (Gifford) Davis, was born at Westport, Mass., on July 31st, 1845. His mother died when he was an infant, and he was reared by a cousin of his grandfather, a maiden lady, Miss Anstrus Baker.

Although his ancestors had been seamen, Mr. Davis' guardian directed his attention to other things. He attended the Grammar and High Schools, of New Bedford, Mass., and when he made inquiries regarding a higher education, he learned that one without means might obtain such an education at the University of Michigan. He went to Detroit, Mich., during the summer of 1864 and found employment on a farm not far from the present town of Dearborn, where he assisted in the clearing of a considerable area of land. On October 1st, 1864, he presented himself for admission to the University of Michigan at Ann Arbor. As he had been able to accumulate only enough money to pay the University fees, he realized that he would be obliged to earn his living expenses and buy his books from funds gained by labor as he pursued his studies. Mr. Davis had become accustomed to hardship during his boyhood, and the difficulties which faced him when he entered the University were met with the sturdy confidence which won for him many a victory in the years that followed.

During the summer of 1867, he was employed by the United States Lake Survey in the measurement of the Portage Entry base line, harbor work, Chocolet River reconnaissance, determination of shore line, inland surveys, and soundings, all on Lake Superior. He was graduated in 1868, his class representing a remarkable group of men, which furnished leaders in engineering, in astronomy, and in the teaching profession. In June, 1868, Mr. Davis entered the office of the City Engineer of Detroit, Mich. In order to be out of doors, he soon resigned and accepted employment with a paving contractor, after which he was engaged, for a short time, in the office of an architect. Since office work did not agree with him, he accepted a position with the Missouri River, Fort Scott, and Gulf Railway, in the fall of 1868, and spent eight or nine months in Kansas under the immediate supervision of the celebrated engineer, the late Octave Chanute, Past-President, Am. Soc. C. E. He returned to Michigan in June, 1869, and during the summer and autumn was occupied in running a railway line from Owosso to Big Rapids, a distance of ninety miles. When this work was completed, he returned to Massachusetts for a visit with his relatives after an absence of six years.

In February, 1870, Mr. Davis returned to Ann Arbor, Mich., where

* Memoir prepared by Clarence T. Johnston, M. Am. Soc. C. E.

he was engaged as Instructor in the Department of Civil Engineering, University of Michigan, until the end of the academic year. He then accepted employment with the Toledo and Ann Arbor Railway and, during the summer, made the location surveys for this line. Later, he accepted the position of Assistant Engineer on the Northern Extension of the Jackson, Lansing, and Saginaw Railway, and made the exploratory surveys from Bay City to Gaylord and the location surveys to Grayling.

In the fall of 1871, he went to Swarthmore, Pa., where he organized a Department of Civil Engineering in Swarthmore College, an institution of the Society of Friends. In June, 1872, he was appointed Assistant Professor of Civil Engineering at the University of Michigan, and began his thirty-eight years of active service as a teacher at his Alma Mater. The late Professor De Volson Wood, the Father of Engineering at the University of Michigan, and Professor Davis' former teacher, had tried to re-organize and improve his Department at Michigan. Failing to obtain the help he had many times requested, he resigned in the spring of 1872, and no argument would induce him to reconsider his decision. His recommendations, however, were almost immediately accepted and the late Professor C. E. Greene, M. Am. Soc. C. E., Professor Davis, and Mr. C. S. Denison were at once appointed to carry them into effect.

Professor Davis bore the title of Assistant Professor of Civil Engineering from 1872 until 1891, when he was made Professor of Geodesy and Surveying. For many years he assisted in the teaching of Descriptive Geometry and Drawing, and he gave one or two courses in Municipal Engineering. Although his practical experience had been largely in railway work, he never encouraged students to specialize therein, holding that engineers had been mistreated by the railway companies.

One of the urgent recommendations of Professor Wood related to the establishment of a camp where students might engage in surveying under field conditions. Professor Davis organized and conducted the first camp of this kind at Whitmore Lake, ten miles north of Ann Arbor, in 1874. It was a course of four weeks. The camp moved from place to place each year, depending on arrangments for the land, transportation, and housing facilities that Professor Davis was able to make. In 1882, the camp was transferred to Old Mission and, from that time to the present, it has always been located in the northern part of the Southern Peninsula of Michigan. It remained a four weeks' course until 1902, when it was extended to six weeks and then to eight weeks in 1909. In 1908, the University acquired 1 500 acres of land on Douglas Lake, near Cheboygan, Mich., thus giving the camp a permanent home. The University of Michigan was the pioneer by many years in the establishment of a surveying camp. The camp now

bears the name of its founder, and it is still conducted in conformity with the rules and regulations which he had developed after long years of experience.

Professor Davis became City Engineer of Ann Arbor soon after his appointment as Assistant Professor of Civil Engineering at the University. This position came to him unsolicited and while he was absent from Ann Arbor. Regardless of political changes, he was retained in office for sixteen years, and when he resigned, his assistant was appointed to succeed him. While City Engineer of Ann Arbor he performed a splendid service. He was unable to convince the City Fathers that the notes of property and general city surveys were matters of great importance and that they should be safely kept in a well-equipped office. He retained all such notes, however, and they are now available and highly appreciated.

He acted as Consulting Engineer for the Flint and Pere Marquette Railway Company and the Toledo and Ann Arbor Railway Company for many years, and he designed and constructed many highway and railway bridges. He also installed water-works systems for several Michigan towns, among which were Greenville and Owosso. His great work, however, was performed in the field of Surveying and particularly Boundary Surveying. He always maintained that "corners were never lost, they were simply not found."

From 1899 to 1902, he had charge of the St. Clair Flats Survey for the State of Michigan. This was a difficult task, and it was completed in accordance with the principles he always advocated and practiced.

Soon after the death of Professor Greene, Dean of the College of Engineering, in 1903, Professor Davis was made Associate Dean. His new duties brought him into contact with every student of the College, and many engineers who attended the University of Michigan during the first decade of the present century will remember the gruff but kindly voice of this fatherly adviser. His new duties were more trying to Professor Davis than his friends generally realized, for his natural sympathy for students who suffer privations made it impossible for him to forget their hardships and trials, day or night, and the indoor work added to his difficulties.

In 1910, he resigned his position at the University and took advantage of the Carnegie pension. In order that he might be near his friends, and yet away from responsibilities, he bought a home in Dexter, Mich., nine miles of Ann Arbor. Some time prior to his resignation, he had purchased a summer cottage on Portage Lake, nine miles north of Dexter, but he and Mrs. Davis generally spent their winters in the South, visiting their son at Birmingham, Ala., and then going to the Gulf Coast. They finally secured a winter home at Bradentown, Fla., where he died on March 9th, 1920.

In July, 1872, he was married to Miss Mary Hubbard Baldwin, of

Ann Arbor, Mich. Three children were born to them, one of whom, Charles Baker Davis, of Birmingham, Ala., with Mrs. Davis, survives him.

Professor Davis never sought favor for himself, but was always active in behalf of others. In 1883, he was elected President of the Michigan Engineering Society and was twice re-elected to the same office. He was also for two years Vice-President of the "Council of Engineering Societies on National Public Works."

He had written little for publication, but he left a great volume of notes relating to the theory and practice of Surveying and to other engineering subjects. He always underrated his ability as a writer, but he was an able reviewer and critic of texts relating to the subjects that he taught.

It is a great satisfaction to all who were so fortunate as to have known Professor Davis to understand that he was happy and contented during his later years. He always said that he desired to quit work some time in order that he might play and do many things that were denied him as a boy. His home was always a welcome place for all his friends and acquaintances. He was always ready to perform some kindly service and no guest ever departed without a higher regard for him and for mankind generally.

Professor Davis was the personification of character and stability. He loved sincerity, truth, and accuracy. His former students will always remember him as an advocate and example of those qualities of the mind and heart which guarantee success in the practice of Surveying and which, possibly in a higher sense, insure happiness and contentment in every walk of life. The principles which he advocated and practiced have been accepted by many who have sat in his classrooms and by many others who are now charged with the duties he so ably performed for the University of Michigan. Those who survive him can perform no higher service for the University of Michigan than that which will result in the perpetuation of the ideals and principles which he exemplified.

Professor Davis was elected a Junior of the American Society of Civil Engineers on April 1st, 1874, and a Member on October 5th, 1898.

JOHN STERLING DEANS, M. Am. Soc. C. E.*

DIED DECEMBER 16TH, 1918.

John Sterling Deans was born at Chester, Pa., on June 25th, 1858, and received his early education in the schools of that place. His father, Charles Woodbury Deans, was engaged in educational work and did much in the early organization of the common school system of the State and in providing school facilities for the orphans of Civil War soldiers. His mother, who survives him, was Priscilla Lyons Williams, of Chester.

The death of his father left Mr. Deans, the eldest of four children, with serious responsibilities early in life, and at the age of 20 years he left the Philadelphia Polytechnic College, before graduation, and took up his life work in his chosen profession.

His first employment was with Clark, Reeves and Company, of Phœnixville, Pa., in January, 1879, at which time this firm was building a large part of the elevated railroad structure in New York City; and, during his subsequent connection with the firm, which afterward became the Phœnix Bridge Company, he saw the development of the modern long-span railroad bridge from the early iron structures that were built during the era of railroad construction which followed the Civil War.

Many noted structures, such as the old Kinzua Viaduct, and the Albany and Greenbush Bridge over the Hudson River, with which Mr. Deans was connected at the outset of his career, were built by the above firm. These were followed by the Red Rock Cantilever Bridge, the Pecos Viaduct, the Rock Island Bridge, the Huntington Bridge, and many others, with which he was connected in various engineering capacities.

Mr. Deans assisted in the design of the Chesapeake and Ohio Railroad Bridge, known as the Huntington Bridge, over the Ohio River at Cincinnati, Ohio, had entire charge of the work in the drawing room, and afterward became Resident Engineer during the erection of the structure, in 1888-89.

This bridge, at the time it was built, contained the longest simple truss span in existence, was double-tracked throughout, with double roadways and sidewalks, and marked an epoch in railroad bridge construction. After the successful completion of this work by the Phœnix Bridge Company, Mr. Deans became Engineer of Erection for the Company, then, in 1891, Principal Assistant Engineer, and, a year later, Chief Engineer. During the time he held this office, a number of large and important bridge structures were built under his direc-

* Memoir prepared by Howard C. Baird and Walter R. Okeson, Members, Am. Soc. C. E.

tion, many of them being designed by the Company and most of them erected by its Erection Department, in which Mr. Deans took great pride and which he brought to a high state of development. The Rock Island Bridge at Davenport, Iowa, the Big Four Bridge at Louisville, Ky., the Cambridge Bridge at Boston, Mass., the steelwork for the Manhattan Bridge over the East River, New York City, and the bridges at Sioux City and Omaha, Nebr., with their long draw-spans, were among the large number of structures erected under his supervision.

He became Vice-President of the Phœnix Bridge Company in 1915, and, in 1917, Vice-President and Consulting Engineer.

As a young man, Mr. Deans' work was marked by extreme care and conscientiousness. His optimistic spirit endeared him to all his associates, and in fact to every one who came in contact with him, and inspired many a beginner to look on the bright side of life and take courage from his example. His fine character and lovable personality had their effect in a marked degree on the young men who came under his authority while he was in command, and all who ever served him treasured the memory of his friendship with an affection equal to their great admiration for his character.

About two years before his death, his health began to fail, and, except for several short periods of apparent improvement, the decline was slow, but sure. In spite of his declining health, however, Mr. Deans was as energetic as ever, and gave unfailing attention to the many duties devolving upon him, undertaking in December, 1917, the work of Chairman of the Steel Fabricators of the United States, an association devoted to aiding the United States Government and the industry in war work. His health continued to decline until the end came, on December 16th, 1918. His youthful spirit and courage remained with him to the last, and the patience which he exhibited during his tedious illness and suffering emphasized the perfect unselfishness that marked his life.

In 1890, Mr. Deans was married to Miss Clara V. Barr, of Cincinnati, Ohio, who survives him. He is also survived by his mother, two sisters, and four children, his two sons having served in the United States Army during the World War.

Mr. Deans was elected a Member of the American Society of Civil Engineers on May 4th, 1887.

FRANK LOUIS FULLER, M. Am. Soc. C. E.*

DIED JANUARY 30TH, 1920.

Frank Louis Fuller, the son of Hezekiah and Emmeline (Jackson) Fuller, was born in Grantville (now Wellesley), Mass., on July 11th, 1848.

As a boy he attended Mr. Allen's School in West Newton, Mass., and was graduated from the Massachusetts Institute of Technology in the Class of 1871.

Immediately after his graduation, Mr. Fuller was employed, under Professor J. B. Henck, on the work of the Massachusetts State Harbor and Land Commissioners on the "Back Bay" District, Boston, Mass., until 1881, when Professor Henck resigned, and he was placed in full charge.

In addition to this work, in 1875, Mr. Fuller opened an office in Boston, Mass., and engaged in private practice as a Consulting and Constructing Engineer. As such he made examinations of the Taunton River Valley for the Massachusetts Board of Health, surveys and plans for the proposed Nantasket Beach Railroad, as well as many other general surveys of roads, rivers, etc.

Mr. Fuller early turned his attention to the design and construction of water-works, and made that branch of his profession a specialty. In that connection, he made plans for and constructed water-works plants for various cities and towns in Massachusetts and the adjoining States, among which were Winchester, Wellesley, Ware, Marblehead, Natick, Webster, West Brookfield, Foxboro, Warren, Uxbridge, Mass., Pawtucket, R. I., Brattleboro and Northfield, Vt., etc. He was among the first to be interested in concrete covered reservoirs and had charge of the construction of such reservoirs in Wellesley and Natick, Mass.

He was also engaged on the construction of the sewerage systems of Swampscott, Marblehead, North Andover, Franklin, and other places in Massachusetts.

Mr. Fuller was married on November 23d, 1882, to Julia Latham Morrill, who survives him. Except for a four years' residence (1882 to 1886) in Boston, he had always made his home in Wellesley, Mass., where he died suddenly on January 30th, 1920, from heart trouble from which he had suffered for several years. On his death the Annual Town Meeting of Wellesley adopted a set of resolutions as an expression of appreciation of his services as a citizen and as a member and Chairman of the Board of Water Commissioners from its establishment. Similar resolutions were also adopted by the Congregational Church, the Congregational Club, and by his associates on the Water and Electric Board of Wellesley.

* Memoir compiled from information on file at the Headquarters of the Society.

He was a man of large outside interests and was always interested and active in various good causes. With Mrs. Fuller he had traveled quite extensively, having made two trips to the Panama Canal, the second of which was a visit to California and included a trip through the completed Canal. He also visited Porto Rico and, in 1913, greatly enjoyed a cruise to the Mediterranean and the Orient, including the Holy Land and the Nile.

Mr. Fuller was a member of the Congregational Church of Wellesley, Mass., which he had served as a Deacon for many years. He was a member of the American Water Works Association, the New England Water Works Association, the Boston Society of Civil Engineers, the Wellesley Club, and the Wellesley Congregational Club.

Mr. Fuller was elected a Junior of the American Society of Civil Engineers on April 4th, 1883, and a Member on April 4th, 1888.

CHARLES EMERSON GREGORY, M. Am. Soc. C. E.*

DIED FEBRUARY 21ST, 1920.

Charles Emerson Gregory was born in Stissing Village, Stanford, N. Y., on February 20th, 1871. He was the son of Edward Benjamin and Julia Wilber (Mosher) Gregory. His paternal ancestor, Johnathan Gregory, came from England in Colonial times and was one of the early settlers of the New Haven Colony. Members of the family served in the Continental Army and one of them fought in the Battle of White Plains. The Mosher family came to America from England soon after the Revolution and settled in New York State.

Mr. Gregory received his early education in the public schools of Stanford and completed his college preparation at the Poughkeepsie Military Institute. He was graduated from Union College, Schenectady, N. Y., in 1894, with the degree of Civil Engineer, and the Engineering Prize.

His first engineering work after leaving college was the construction of a system of water-works at Coxsackie, a drainage canal at Middleport, and water-works at Red Hook, N. Y., all of which was accomplished during 1894 to 1896. In March, 1896, Mr. Gregory entered the employ of the City of New York, in the service of which he was a useful member for many years. At first he was an Engineer Inspector in the Department of Public Works, inspecting the repaving and the laying of water mains in Fifth Avenue; later, he became a Transitman in the office of the Commissioner of the 23d and 24th Wards, now known as the Borough of the Bronx, and, in September, 1898, he was appointed Assistant Engineer in the Sewer Bureau of the Borough of the Bronx where he served about five years in charge of sewer construction and three years in charge of the design of the new sewer system for the easterly portion of the Borough, a drainage area of about 7 000 acres. This included some of the most extensive and difficult sewer work in the City of New York and the design of some of the largest reinforced concrete storm-water drains ever built up to that time. It was then that Mr. Gregory began his studies of rainfall and run-off which continued a matter of special interest to him throughout his whole life. This interest was stimulated by a friendship with the late Emil Kuichling, M. Am. Soc. C. E., which began about this time—a friendship so helpful to both in regard to sewer design and run-off problems. From this time, also, Mr. Gregory was never without a little pocket-book in which were entered all sorts of observations, notes, calculations, and diagrams relating to this,

* Memoir prepared by Arthur H. Pratt, M. Am. Soc. C. E.

to him, ever-absorbing subject. It is to be regretted that a busy life prevented the orderly assembly of this material for publication by the Society, as he had always intended, although much of it has appeared in fragmentary form in discussions of various papers.

In the spring of 1906 Mr. Gregory joined the staff of the Board of Water Supply of the City of New York as Designing Engineer. Under Chief Engineer J. Waldo Smith, M. Am. Soc. C. E., he prepared the designs for the Ashokan Reservoir, including the Olive Bridge Dam and the extensive earth dikes, the Kensico Dam and Reservoir, and the Silver Lake Reservoir. Among the various appurtenant works to these main structures were ten concrete bridges designed in collaboration with the Board's Architect, H. Lincoln Rogers, Assoc. M. Am. Soc. C. E., the most notable of which are the beautiful Traver Hollow and Rye Outlet Bridges—the former a spectacular three-hinged, single arch of 200 ft. span, and the latter a 1 000-ft., five-span structure.

In 1912, on the request of Mr. George McAneny, then Borough President of Manhattan, Mr. Gregory was transferred to the Borough President's office as Deputy to Consulting Engineer Ernest P. Goodrich, M. Am. Soc. C. E. Here, Mr. Gregory was closely associated with all the numerous public improvements proposed and in progress at that time. One of the best known was the removal of the long-standing building encroachments in Fifth Avenue, 42d Street, 34th Street, and elsewhere. This work included not only the approval of the plans and inspection of the execution of the work, but also the delicate matter of securing the co-operation of the owners in spending their own money for the improvement. The Borough President during that administration was a powerful factor in the rapid transit problem and his Consulting Engineer advised on the development of the plans for the new subway systems for the Greater City. Among the many strictly Borough matters taken up at this time were the establishment of new policies for the Bureau of Buildings and the new repaving programme for the streets of the Borough. Plans for remodeling High Bridge over the Harlem River to conform to the War Department requirements were prepared by Mr. Gregory, and the work is now being pushed along lines similar to his original ideas. During the Administration of the late Mayor Mitchel, the Consulting Engineers of the five Boroughs and the Chief Engineer of the Board of Estimate and Apportionment were constituted a Board for the consideration of many of the general engineering problems of the city, and Mr. Gregory served as Secretary to this Board, in addition to his other duties.

In 1913, the City Administration appeared to be ready to take up actively the sewerage problems which had been pressing for a long time. The Metropolitan Sewerage Commission had made its report

recommending the Ocean Island project, much publicity had been given to the subject, and several members of the Board of Estimate and Apportionment seemed particularly interested in the sewerage question. The whole matter was referred to the Board of Consulting Engineers, and after considerable discussion and some controversy finally resulted in the Metropolitan Sewerage Commission making its final report and going out of office, turning over its data and studies to a new establishment called the Bureau of Sewer Plan of the Board of Estimate and Apportionment. This Bureau was under the direction of the Board of Consulting Engineers, Nelson P. Lewis, M. Am. Soc. C. E., Chairman. Mr. Gregory was appointed Secretary and Executive Officer, a staff was organized and a scheme of sewage disposal for the entire city prepared.

In 1914, Mr. Gregory was appointed Chief Engineer of Sewers of the Borough of Manhattan. During the next four years he re-organized the Sewer Bureau on a modern basis, installed businesslike and efficient methods of sewer maintenance, introduced the motor truck mounted pump for cleaning out receiving basins, began the division of Manhattan's sewers into drainage districts leading to a harmonious scheme of sewage treatment, continued the studies of harbor pollution begun by the Metropolitan Sewerage Commission, made many specific recommendations for the mitigation of long-standing nuisances, and had drainage plans prepared for many areas of the Borough where the drainage situation had been particularly bad for years. During this time, the remarkable long-time, Central Park, rainfall intensity records were compiled and studied. Although these records were published by the Rainfall and Run-off Committee of the Municipal Engineers of the City of New York, the data were prepared for publication under Mr. Gregory's direction, as was also the greater part of the Committee's report. The rational method for the design of storm-water sewers was instituted in Manhattan by him and a new run-off curve was adopted, based on the Central Park rainfall curves and sewer gaugings made under his direction, all modified by his firmly established judgment in these matters. A new method of computing the dry-weather flow was also developed, based on the probable future growth of the Borough, now more susceptible of prediction, on account of the newly adopted Zoning Law, and the water consumption determined on a basis of anticipated floor area.

When it comes to the actual authorization of sewer improvements in New York City, it is very desirable to obtain the interest and co-operation of the property owners, as all such work is paid for by local assessment. In this matter, Mr. Gregory was pre-eminently successful, due to his tact and personality, so that by enthusiastic, individual effort on his part he was able to bring many of these improvements

to a conclusion or well beyond the first stages of authorization. Among the sewers finally authorized, the most notable are the West 46th Street tunnel, the East 41st Street storm relief sewer, and the Canal Street District separate system. The use of sewers for snow removal was instituted in New York City while Mr. Gregory was in charge of the Department. He collaborated with the then Commissioner of Street Cleaning, J. T. Fetherston, M. Am. Soc. C. E., in the early snow disposal experiments, and the final success of the sewer disposal method was due very largely to Mr. Gregory's hearty co-operation.

In 1914, Mr. Gregory was sent to Europe by the Borough to observe the sewage disposal plants of France, England, and Germany. On his return, he designed and constructed the first sewage treatment plant to be built in the Borough of Manhattan. It is of the revolving disk, screen type and is located on the Hudson River at the foot of Dyckman Street, in the Inwood District, and is housed in an ornamental building which sets a new precedent in sewerage structures for New York City. The operation results of this plant were published in articles prepared by him for the *Engineering News-Record*. This plant was to have been the first of a series of appropriate sewage treatment units designed to be built at various locations around the borders of Manhattan Island, in accordance with a general harmonious disposal scheme for the Greater City, in the preparation of which Mr. Gregory had been so largely instrumental.

All this work was interrupted by the war, and in April, 1918, Mr. Gregory joined the staff of the Air Nitrates Corporation. He was Assistant Resident Manager at the Muscle Shoals Plant for a time and, later, became Chief of the Civil Engineering Bureau, in which position he was responsible for an enormous amount of building, power-house, machinery, railroad, dock, water supply, drainage, and road construction work in connection with the ammonia nitrate plants at Cincinnati and Toledo, Ohio.

Mr. Gregory retired from this work and returned to New York City in January, 1919, when he was appointed Engineer of Drainage and Sewage Disposal of the Borough of Manhattan and assigned by the late Borough President Dowling to complete his previous studies and finish the long-delayed "comprehensive plan" for the collection and treatment of Manhattan's drainage.

For many reasons it appeared to Mr. Gregory unlikely that the "plan" would be executed for a long time to come, so in June, 1919, he resigned from the City service to accept an appointment as Deputy Engineer with the North Jersey District Water Supply Commission which was beginning the comprehensive development, under State supervision, of the remaining potable waters of Northern New Jersey. In the few months that he was spared on this work, he completed the

designs for the Wanaque Dam and appurtenant works which will make the water of the Wanaque River available as a supply for the City of Newark and neighboring towns. The contract for this work was completed and ready for advertising when Mr. Gregory died at his home in East Orange, N. J., on February 21st, 1920.

The esteem in which he was held in his last engagement is shown by the following resolution passed by the Commission:

"*Resolved:* The Commissioners of the North Jersey District Water Supply Commission desire to record their appreciation of, and esteem for, its late Deputy Engineer, Charles E. Gregory. They gladly bear witness to his sterling worth, professional standing, and high character. His extensive knowledge of his profession, his knowledge of men and rare tact were of great value in the work of the Commission. His courtly manner and genial disposition made him an esteemed and valuable officer. His work with the Commission, and before such association, was widely recognized as of a consistent and constructive type and remains a lasting memory to him.

"He was of the type of men who leave behind them memories that endure, and we take this opportunity to record in our minutes this testimony of our esteem and affectionate regard for one who was more than an employe, and of his worth as an Engineer and Citizen."

Mr. Gregory was a frequent contributor to the Society's discussions, especially on drainage and water-works subjects. He was also an esteemed writer on these matters for the engineering press. He was a member of the Beta Theta Pi Fraternity, the Masonic Order, the American Water Works Association, the New Jersey Sanitary Association, and was a Past-President of the Municipal Engineers of the City of New York.

For many years, Mr. Gregory had lived at Mt. Kisco, N. Y., where he was an active and honored citizen. He had served as Trustee of the Mt. Kisco Board of Education from 1910 to 1916, having been President of the Board for the last two years, during which time the new main school building was erected and many improvements were made in the school system. He was an Elder of the Mt. Kisco Presbyterian Church for twelve years.

On October 15th, 1896, Mr. Gregory was married to Frances Gurney Sackett, of New York City, and she and their three children—Robert Douglas, Charles Emerson, and Frances Eleanor—survive him.

In personal characteristics, Mr. Gregory was generous, genial, conscientious, and sincere. His generosity was shown by his unfailing respect for and consideration of subordinates; his ever-willingness to listen to their side of the case; his recognition of the most subordinate assistant as a collaborator on every problem. Few engineers can command the respect and admiration, together with the true affection, of their assistants, as did Mr. Gregory. His calm and unruffled per-

sonality were important characteristics; he was always under firm self-control, even under the most exasperating circumstances. The most annoying and troublesome matters were settled fairly, justly, and without malice. He had a winning smile and a kind word for every one, but with these was the firm hand, when firmness was needed.

His gentle persistence, always avoiding needless controversy, but never fearing to keep to the right, enabled him to put through by sheer, personal effort many things where a more openly aggressive personality might have failed. This was especially noticeable in connection with sewer matters in Manhattan where every improvement had to be carried through the many steps of approval by various boards and officials. The citizens of New York City have Mr. Gregory to thank for such improvements as the Dyckman Street screening plant. He had a peculiar ability to accomplish results under the trying and difficult processes of New York's public works system. One of his associates has said:

"Mr. Gregory possessed, in a remarkable degree, the ability to co-operate with others, eliminating all personalities for the end to be accomplished. He was extremely modest in personal demeanor, yet courageous in stating his position on any controversial subject, and he persistently followed fundamental truths and laws in all his activities. He was a man of character, culture, and ability. His capacity for securing results was exceptional."

As an engineer, he was progressive and open-minded and most thorough—every condition was considered, every possible solution investigated. He was always willing to adopt new things if they were good, but never solely on account of their novelty. There was none of the "good enough" spirit about Mr. Gregory—it must be "right". He was an entertaining companion, but disposed to lead the conversation to serious topics. He was open-minded to new ideas in philosophy and government and sincerely interested in all that would improve the social fabric.

Deeply conscientious and serious, with high ideals as to his duties to his family, the community, the State, and to his God, the personality of Charles E. Gregory will forever be a precious memory to every one who had the privilege of being associated with him.

Mr. Gregory was elected a Junior of the American Society of Civil Engineers on October 6th, 1896, an Associate Member on March 6th, 1901, and a Member on June 19th, 1918.

JAMES CURRIE HALLOCK, M. Am. Soc. C. E.*

DIED NOVEMBER 2D, 1918.

James Currie Hallock was born in Treasure City, Nev., on December 8th, 1869. After completing his preliminary studies in his native State, he entered Rensselaer Polytechnic Institute, Troy, N. Y., from which he was graduated in June, 1891, with the degree of Civil Engineer.

Shortly after his graduation, Mr. Hallock entered the service of the Troy Steel and Iron Company of Troy, N. Y., as Assistant to the General Superintendent, remaining until February, 1893, when he entered the employ of the United States Coast Survey Corps which was engaged in deepening the Hudson River for a ship channel, and had charge of the drilling and blasting of a reef at Saugerties, N. Y.

In July, 1893, Mr. Hallock accepted a position with the Government of Ecuador, and until November, 1894, he was Government Engineer and Surveyor-General of the Province of Esmeraldas. In November, 1894, he was employed as Assistant Engineer by the Playa de Oro Mining Company, of Esmeraldas, Ecuador, remaining with that company until May, 1895.

In June, 1895, Mr. Hallock began private practice as Mine Examiner and Expert in San Francisco, Cal., where he remained until August, 1901, when he returned to Ecuador as General Manager of the Southern Exploration and Commercial Company of Ecuador. In October, 1901, he again entered the employ of the Government of Ecuador, as Government Engineer of the Province of Esmeraldas, which position he held until February, 1903, when he was made Director General of Public Works and Chief Engineer for the Government of Ecuador, his duties covering the general supervision of public works, such as the construction of highways, bridges, canals, sewerage and water supply systems, public buildings, etc., as well as the inspection and approval of all railroads and other work being done by contract. Mr. Hallock held this position with great credit to himself and the Government until February, 1906, when a revolution took place, throwing the party by whom he was employed from power. When the Government Palace was surrounded by revolutionists, he succeeded in getting through their lines and saved a number of Government records which he turned over to the American Consul.

Returning to the United States, Mr. Hallock became Engineer in charge of field work with the Passaic River Flood Commission of New Jersey, taking up his duties with this Commission in June, 1906. On the completion of this work, he accepted the position as Assistant Chief Engineer of the New Jersey State Water Supply Commission, and, on

* Memoir prepared by M. R. Sherrerd, M. Am. Soc. C. E.

March 1st, 1909, was made Assistant to the Chief Engineer of the City of Newark, N. J. In February, 1910, the Board of Works created the position of Deputy Chief Engineer, and on February 17th, he was appointed to that office.

In his new position, Mr. Hallock was given direct charge of the meadow reclamation work and the general development of the Port Newark Terminal. The demonstrated availability of the great tract for industrial use is pointed to as a testimonial to his foresight and efficiency. In addition, he was the active head of the City's garbage collection and disposal system, a work in which he also met success.

Possessing a pleasing personality and enjoying widespread popularity, he was active in the civic affairs of Newark, N. J., in addition to his work in an official capacity. He was Chairman of the Executive Committee of the Mayor's Council for National Defense and instrumental in organizing the Home Defense units of the city.

Mr. Hallock severed his connection with the City of Newark in February, 1918, and returned to Ecuador to become Engineer to that Republic. As such his chief task was the suggestion of a system of flood control to curb the annual floods in the River Jubones and to end this serious menace to the chocolate plantations located along that river. Before his death, which occurred in Ecuador on November 2d, 1918, he had submitted a report to the Government for a general scheme to effect such control and was in charge of the inauguration of the work.

He was an active member of the American Society for Municipal Improvements and assisted materially in formulating many of the standard specifications adopted by that Society. He was also a member of the Engineers' Club of New York City and Vice-President of the Traffic Club of Newark, N. J.

Mr. Hallock was elected a Member of the American Society of Civil Engineers on October 3d, 1906.

WILLIAM JOSEPH HARDEE, M. Am. Soc. C. E.*

DIED NOVEMBER 17TH, 1918.

William Joseph Hardee was born on March 27th, 1863, in Brandon, Miss., at which place his parents resided temporarily during a part of the time of the Civil War. He was the first of ten sons born to Thomas Sydenham Hardee, of Savannah, Ga. (himself a Civil Engineer of high reputation), and Harriot Sophia Zacharie, of New Orleans, La. He was a nephew of Gen. William Joseph Hardee of the Confederate Army, and was named for that distinguished man.

In early childhood Mr. Hardee's parents moved from Brandon to New Orleans, and there he received his preparatory schooling. After his professional education, his first work was with the old New Orleans and Pacific Railroad, later known as the Texas Pacific. In 1866 he became connected with the United States Engineering Department, as Assistant Engineer, and for nearly fifteen years was engaged on hydrographic and topographic work on the Mississippi River from Vicksburg to the mouth, including charge of the location, construction, and maintenance of the great levee system in that territory.

In 1899 Mr. Hardee was elected City Engineer of New Orleans, which position he held until his death. During his eighteen years as City Engineer, New Orleans undertook and accomplished more construction work than in any other period of its history, and many of its prominent public works are monuments to his skill and professional ability. It was under his administration and supervision that the great harbor belt-line project was started and completed, the chain of old public school buildings replaced by modern structures, the street paving throughout the city brought up to metropolitan standards, including a municipal repair plant, and many of the public parks and playgrounds created. Notable among these improvements is the sea wall and park at West End, which was designed and constructed under his direction.

Capt. Hardee died after a brief illness resulting from epidemical influenza. His life had been devoted to his profession in which he had attained a place of distinction and National prominence. He was a veteran of the Spanish-American War, having volunteered for service at the outbreak of those hostilities, and was commissioned by President McKinley, Captain of Company F, Third Regiment, U. S. Volunteer Engineers.

Capt. Hardee was a Member of the Louisiana State Society of Engineers, and of the National Association of City Engineers. He was twice President of the latter Association, and at the time of his death was an Honorary Vice-President of the organization. He was elected a Member of the American Society of Civil Engineers on May 6th, 1896, and was the oldest New Orleans member of the Society.

* Memoir prepared by George W. Hardee, Esq.

JAMES HAYWARD HARLOW, M. Am. Soc. C. E.*

DIED OCTOBER 6TH, 1918.

James Hayward Harlow, was born in Westminster, Worcester County, Mass., on September 30th, 1846. He died at his home at Darlington, in the Fifth District of Harford County, Maryland, on October 6th, 1918. Like many another of the old New England stock, he could trace his ancestry to the *Mayflower*, being the tenth in descent from Richard Warren and the ninth from John Alden and Priscilla Mullins.

His father, Noah R. Harlow, was a civil engineer, and was engaged on the location of the Nashua and Lowell Railroad, one of the first roads built in the United States. Later, he was Assistant Engineer in charge of the Fitchburg Division of the Vermont and Massachusetts Railroad, and, in 1854, Chief Engineer of the Terre Haute, Alton and St. Louis Railroad. In 1856 he returned to Massachusetts and for much of the time until his death in 1892 was Engineer and Paymaster of the Proprietors of Locks and Canals, at Lowell, Mass.

His mother was Sarah Ann Hunt, daughter of Asa and Maria F. (Hollis) Hunt. She died before he was a year old, and his father married Sarah Caroline Howe. Under her charge he never lacked a mother's love and care.

As a boy James Hayward Harlow was not strong, and attended school but little, having been taught at home. His mathematics he acquired by private study, and his primary engineering knowledge by helping his father. In 1863, he worked in a small machine shop in Leominster, Mass. While here he gained such skill in the handling of tools that, later in life, when he did a little filing, the machinists remarked that he had done that thing before and knew how to hold a tool.

In 1864 Mr. Harlow's family moved to Lowell, Mass., and he was employed for about a year in the office of the Proprietors of Locks and Canals. In 1865 he commenced his engineering work in the employ of the Franklin Company, at Lewiston, Me., the corporation owning the water power of the Androscoggin River. He remained there two years. In 1867 and 1868 he was at Davenport, Iowa, in the employ of the United States Government, on the improvement of the Mississippi River. In 1869 he was under Gen. Rodman, in the U. S. Arsenal at Rock Island, Ill., and he also spent some time in this vicinity on a railroad survey. In 1871 he returned to Lowell and was Assistant Engineer in charge of laying the pipe lines of the original plant of the Lowell Water-Works. In 1872 he was Assistant Engineer in charge

* Memoir prepared by George R. Harlow, M. Am. Soc. C. E.

of laying the pipe lines for the "new" water-works at Pittsburgh, Pa., and remained there until May, 1874.

Mr. Harlow then opened an office in Boston, with the late Gorham P. Lowe, M. Am. Soc. C. E., as partner, but this partnership was dissolved in 1876. For the next two years he was with the engineering force on the Metropolitan Water Supply, being at South Framingham, Mass., for much of the time. In August, 1878, he was appointed Assistant Engineer under Lieut. Mahan, who had charge of building the Davis Island Dam, in the Ohio River just below Pittsburgh. The pool made by this dam extends to Dam No. 1, on the Monongahela River, and makes a harbor for the coal boats at Pittsburgh. Under Mr. Harlow's supervision, the lock walls were built and the foundations for the dam commenced. The appropriation having been spent, he was asked to resign in January, 1880.

Again he opened an engineering office, this time in Pittsburgh, Pa., where he made his headquarters until he moved to Maryland, in 1902. He helped to organize the New Castle Water Company in 1881, and designed and superintended the building of its water-works at New Castle, Pa., in 1881 and 1882.

From 1881 to 1885 Mr. Harlow was Chief Engineer of the Monongahela Navigation Company, in charge of the construction of the dams and locks on the Monongahela River. Under him the new Dam and Lock No. 7 and the second lock at Dam No. 3 were built. In 1884, he was made President of the Water and Gas Works Construction Company, with offices at Pittsburgh. This Company built the water-works at Elkhart, Ind., in 1884, Eau Claire, Wis., and Mattoon, Ill., in 1885, and Latrobe and Mercer, Pa., in 1886. In this latter year they built a large gas pipe line through some of the principal streets of Pittsburgh. This contract was disastrous, and the Company was dissolved in 1887. In this year he entered into partnership with his two younger brothers, George R. and Edward J. Harlow, under the firm name of James H. Harlow and Company, Engineers and Contractors. They built water-works in Canisteo and Port Henry, N. Y., Tarentum, Etna, Waynesburg, Millvale, and Homestead, Pa., and Annapolis and Bel Air, Md.

In 1888, Mr. Harlow acquired the charter of the Pennsylvania Water Company, the company which now supplies the municipalities adjoining Pittsburgh on the east. Under his management, the capitalization of this company grew from $300 000 to $2 250 000. In 1889, when the works were first built, there were 14 miles of pipe lines, none larger than 16 in. In 1902 there were 102 miles of pipe lines, including about 3 miles of 42 and 36 in. In this latter year he sold his interest in the corporation to the Mellons, of the Mellon National Bank of Pittsburgh.

In 1894 Mr. Harlow's attention was called to the water-power possibilities of the Susquehanna River between Columbia, Pa., and its mouth. From being an engineer he became also financially interested in acquiring properties along its shores. He and his associates sold their holdings in Pennsylvania to the builders of the dam at Holtwood, now operated as the Pennsylvania Water and Power Company. In 1915, this company delivered in Baltimore 343 000 000 kw-hr. of electric power.

After 1904 Mr. Harlow resided at Darlington, Md., and was Chief Engineer of the Susquehanna Power Company, which controls the Susquehanna River from the tail-race of the dam at Holtwood to its mouth. When this part of the river is developed, it will produce twice as much power as that delivered by the Pennsylvania Water and Power Company in 1915. He owned all the capital stock of the Havre de Grace (Md.) Electric Company, and was its Treasurer. He also owned the electric plant at Perryville, Md., which he operated as the Perryville Electric Company. In addition to the enterprise just mentioned, his advice was sought and given in many water-power and other hydraulic cases.

Thus far, reference has been made only to Mr. Harlow's engineering work. While at the Davis Island Dam he was one of the organizers of the Engineers Society of Western Pennsylvania, and was its first Secretary, from 1880 to 1884, and again in 1891. He was a member of the Engineers Society of Pennsylvania, of Harrisburg, and of the Engineers Club of Baltimore. He was one of the founders of the Pennsylvania Water Works Association, had been its President, and, up to 1902, had served on its Executive Committee.

Mr. Harlow was one of the Charter Members in 1890 of the Edgewood Church, of the Pittsburgh Presbytery, and was President of its Board of Trustees until 1902. He was a member and supporter of Harmony Presbyterian Church, near Darlington, a member of Darlington Grange, the Darlington Good Roads League, the Darlington Civic Association, the Darlington Cemetery Company, and the Community Council of Defense, and organized the Darlington Creamery Company. His ability as a farmer is shown by the fact that when he bought his home place, of 32 acres, it would not keep three horses and two cows without having to buy feed; but in 1914 he built a large barn, and the place now sustains three horses and eight cattle. Mr. Harlow had served as Foreman of the Grand Jury of Harford County, and had investigated rumors of misdoings among the officials, to the satisfaction of the Court and County.

These connections show how widely his interests extended. How he was esteemed by his associates is shown by the following memorials presented after his death.

The Pennsylvania Water Works Association said:

"And because of his genial, lovable personality, his presence was always welcome."

The Directors of the Baltimore County Water and Electric Company said:

"The Board of Directors have had taken from their number a sincere and beloved friend and adviser, whose broad experience and ripe judgment was ever sought and relied upon. His hearty co-operation, coupled with his untiring energy and constant alertness for the upbuilding and success of the enterprise in which he had so keen an interest, was always at the command of the Company, and frequently at great personal sacrifice.

"Always willing and anxious to serve in any capacity for the general good and substantial progress of the community of which in the later years of his life he so completely made himself a part, the State of Maryland has lost a man whom it will be difficult to replace."

The Darlington Grange said:

"* * * Brother Harlow put his trust in God, living a quiet, undemonstrative, but effective Christian life. He nurtured hope, being essentially optimistic, both by nature and conviction. He dispensed charity, was kind to those in need, especially seeking to help men to help themselves. And in all this community, and wherever he was known, he was noted for his fidelity; honorable in all business transactions; faithful to every covenant and agreement."

The Home and Foreign Missionary Society of Harmony Church said:

"* * * We came to appreciate his worth as a Christian man, and the value of his counsel and aid in all our church enterprises. And we are deeply sensible of the loss which the Church as well as the community has sustained by his removal."

The Community Council of Defense, of Dublin Precinct, Fifth District of Harford County, said:

"We cherish the memory of his noble character, his fine Christian spirit, his lofty patriotism, and the wisdom of his counsel."

John A. Walls, M. Am. Soc. C. E., Chief Engineer of the Pennsylvania Water and Power Company, in a letter to Mrs. Harlow, said:

"I feel that in Mr. Harlow's death I have lost a great friend and the world a business man and engineer of high integrity and ability. I cannot tell you how much I have appreciated the friendly counsel given from his mature experience. With pleasure I looked forward to his occasional visits here, for he was always willing to help us somewhat younger men in those of our problems that had been his. His ready acceptance of the new, tempered by a just appreciation of the older established principles in engineering work, made his viewpoints particularly interesting and valuable. I count it a privilege to have known him."

He was married on April 11th, 1872, to Thursa Alice Butler, of Pelham, N. H., who, with their four children, survives him. The oldest child is James H. Harlow, Jr., Assoc. M. Am. Soc. C. E., President of the Havre de Grace Electric Company, at Havre de Grace, Md. The second is Florence Harlow, wife of George F. Rowell, M. Am. Soc. C. E., of Philadelphia; the third is Justin E. Harlow, in charge of the electric current at a sugar refinery at Clinton, Iowa; and the fourth is Miss Alice Harlow, who is a graduate of the Nurses Training Course at Johns Hopkins Hospital, Baltimore. He had eleven grandchildren.

Mr. Harlow was elected a Member of the American Society of Civil Engineers on March 4th, 1874.

WILLIAM APPLETON HAVEN, M. Am. Soc. C. E.*

DIED JANUARY 6TH, 1919.

William Appleton Haven, the twelfth child of William Haven, merchant, and Sophia (Henderson) Haven, was born in Portsmouth, N. H., on August 12th, 1831. One of his ancestors, Richard Haven, who came to Lynn, Mass., from England on August 23d, 1643, was a carpenter, and worked in several of the new settlements. It is recorded that he built a house in Boston, and refused as part payment therefor a considerable tract of land in that city. As Boston then consisted of three hills, separated by swamps, the prospective value of the land offered did not appear to be as great as that of the house. He went inland about 15 miles, to what is now Framingham, known then, as now, as the "grassy lands", well watered by springs, and there settled and married.

On August 23d, 1843, William Appleton Haven went with his father to Framingham, to attend the second centennial anniversary of the arrival of Richard Haven in America. There were present more than 1000 of his descendants, comprising the majority of the foremost inhabitants of that part of Middlesex County in which Framingham is situated. No very rich people were among them. They were farmers, tradesmen, ministers, doctors, lawyers, members of various conventions, and early legislators, and it was noted that, for nearly two centuries, there had never been a year in which some descendant of Richard Haven had not been a student at Harvard College.

At about the same time as Richard Haven arrived in Lynn, Thomas Appleton, who traced his ancestry in England back several centuries, came to Ipswich, Mass., and there built a tide-water mill. Many of his sons were graduated from Harvard, and, in 1750, Nathaniel Appleton, D. D., LL. D., was President of that college. His daughter, Mehitable Appleton, was married to the Rev. Samuel Haven, D. D., in 1753. One of the children of this marriage was William Haven, the father of William Appleton Haven.

The elder Haven, at the age of fifteen, was sent to a West India port as a supercargo, continuing to other foreign ports, until the embargo under President Jefferson put a stop to all foreign commerce. He then organized and conducted the first marine insurance company of Portsmouth. When foreign business began again he became supercargo for W. H. and J. Haven, making trips to Calcutta, Marseilles, Buenos Aires, and Savannah. In 1820 he was appointed cashier of the New Hampshire Bank, continuing until the expiration of the charter in 1852.

* Memoir prepared by Emile Low, M. Am. Soc. C. E.

William Appleton Haven attended private schools until he was fifteen, and then went to Boston, where he was apprenticed for two years with the firm of Brown and Hastings, Civil Engineers and Land Surveyors. On May 10th, 1849, he left Boston, and traveled by railroad to Montpelier, Vt., the temporary terminus of the Central Vermont Railroad, thence by stage to Burlington, by steamboat to Plattsburg, and by stage to Ellensburg, where he took a position as Rodman on the Northern Railroad of New York, then being built from Ogdensburg to Rouses Point (Ogdensburg and Lake Champlain Railroad). The next year he became Leveler, and remained on that railroad until its completion, in the fall of 1850. He then returned to Portsmouth to pursue his studies in civil engineering.

Early in May, 1852, with $50 in his pocket, Mr. Haven started for the West, to get engineering work. His money was soon spent, but his pluck increased, and in June, after many disappointments, he at last found himself in Marquette, Mich., without a cent in his pocket, but with an engagement as Transitman on the survey of the Marquette and Green Bay Railroad, the first railroad projected on the shore of Lake Superior. He was employed on this survey until the work stopped, in August. In the following October, he became Assistant Engineer on the Galena and Chicago Union Railroad, and then Resident Engineer and Roadmaster on the Beloit and Madison Railroad, remaining until 1857. Then he took charge of a locating party on the Milwaukee and La Crosse Railroad. These lines are now parts of the Chicago and North Western Railway.

During 1858 Mr. Haven was Principal Assistant Engineer of the Little Rock and Fort Smith Railroad, in Arkansas, now part of the Missouri Pacific Railway. In 1859 he was a member of the firm of Haven and Ames, Surveyors and Civil Engineers, in private practice in Bloomington, Ill. In the spring of 1860 he was appointed Chief Engineer of the Houston, Trinity and Tyler Railroad, now a part of the International and Great Northern Railroad, but construction was suspended in December, 1860, "until the troubles in South Carolina blow over." Mr. Haven's headquarters and residence were at Harrisburg, a small village about 6 miles south of Houston, Tex., and he, being a legal voter, as well as a Northern man, in January, 1861, was honored by being taken in a carriage, with an armed escort, to the voting place, where he cast one of the 124 ballots "for secession" (the vote in that town was unanimous). The next day he was requested (a "request" to a Northern man in Texas from the Committee of Safety in 1860-61 would nowadays be called an imperative "order") to join the "Harrisburg Guards", in charge of Capt. "Poker" More. Mr. Haven never knew Capt. More's real name, but his cognomen was given on account of his proficiency in his favorite game.

As a private in this company, Mr. Haven drilled three times a week, and so learned "Scott's tactics." At that date there were neither railroads nor telegraphs connecting Texas with the other States, but steamships arrived at Galveston twice a week with mails, and the news was immediately telegraphed to Houston. On steamer days all the male population of Harrisburg gathered around the railroad station where the telegraph operator intercepted and read aloud the news from the "States." Mr. Haven used to join in the cheers for the South and hisses at the Northern mudsills, "who are afraid to fight."

One morning in April, 1861, the operator read off something that raised louder cheers from the crowd, but made Mr. Haven realize that Texas was no place for him: the news from Fort Sumter; the call for 75 000 men; the movement of the regiments of Massachusetts; the action of the Legislature of New York; and that the whole North was responding to the call of President Lincoln. Following this came orders for the Harrisburg Guards to be ready to start for Galveston the next day, and thence "on to Washington." Luck and pluck enabled him to desert ignominiously from the Guards that evening and catch the steamboat for Galveston. The next day at noon he was on an ocean steamer, outside of Galveston bar, bound for New Orleans. Thence he traveled quickly by river and railroad to Portsmouth.

Mr. Haven remained at home with his mother and sisters during 1861 and until August, 1862, and then, with Joseph H. Thacher and George T. Wilde opened a recruiting station and called for volunteers. They set up a tent on the Parade, hoisted a flag, and got a disabled soldier of the 2d New Hampshire Volunteers to teach "Hardee's Tactics" and drill them and the recruits in the evenings in Jefferson Hall. In October of that year, with about 75 men, they went to the State camp in Concord, and soon became known as Company K, 16th New Hampshire Volunteers, Mr. Haven being Second Lieutenant.

Lieut. Haven was for a time on duty with his regiment at Butte-a-la-Rose, La., but when the fort was abondoned and the barracks burned, he was delirious with fever and had to be carried to the steamboat. Still burning with fever on arrival at Algiers, Lieut.-Col. Fuller and a lieutenant of Company A, carried him to New Orleans, where he was attended by Dr. Lurton, a skilful resident physician. Lieut. Haven, too sick to join the regiment when it was ordered home, was sent to New York by steamship. He met his regiment at Concord, and was mustered out of service on August 20th, 1863. His fever was followed by dropsy and then by varicose veins.

During the fall and winter of 1863, Mr. Haven bandaged his leg and limped about Portsmouth, but in the early spring of 1864 he obtained employment as Assistant Engineer on a railroad in Connecticut. Then, in the summer, finding that he could work 14 hours a day, and take long tramps, and thinking he could still render some service

in the army, he resigned his position and returned to Portsmouth. There he recruited a few young men and went with them to Concord, where he received a commission as First Lieutenant of Company D, 18th New Hampshire Volunteers. His regiment went to Virginia, and he remained on duty until mustered out in June, 1865.

After passing the summer in Portsmouth and Gosport, Mr. Haven again became actively engaged in engineering. During 1866-67 he was Locating Engineer on the Oswego and New York Midland Railroad (now New York, Ontario and Western Railroad); in 1868-69 he was Chief Engineer of the Dixon, Peoria and Hannibal Railroad, in Illinois; and in 1870-71, Chief Engineer of the Chicago and Michigan Lake Shore Railroad, a line from Chicago to Holland, Mich.

In 1871 he was appointed Chief Engineer of the Buffalo, New York and Philadelphia Railroad (now part of the Pennsylvania Railroad), locating and constructing the line between Olean, N. Y., and Emporium, Pa., on the Philadelphia and Erie Railroad, remaining on this work until the end of 1872.

During the winter of 1872-73 he was Assistant Engineer of the New York Central and Hudson River Railroad, stationed at Rochester, N. Y., on double-track work. On April 25th, 1873, he was appointed Chief Engineer of the Wisconsin Central Railroad, and stationed at Stevens Point, Wis. The panic of 1873 caused the suspension of all work on this railroad, and in 1874 he returned to Rochester, N. Y., where he owned a home. For several years he was engaged in a manufacturing enterprise, but took up engineering again in 1877, when he was appointed Chief Engineer of the Brattleboro and Whitehall Railroad, a line in Southeastern Vermont, now operated by the Central Vermont Railroad.

In the fall of 1878 Mr. Haven was appointed by the Second Vice-President of the New York, Lake Erie, and Western Railroad (now the Erie Railroad), as Engineer in charge of construction of the Buffalo Division. He commenced his duties in Buffalo, N. Y., in January, 1879, having had charge of double-tracking from Burns to Attica, Buffalo terminals, elevators, docks, coal pockets, East Buffalo improvements, and shops. This work was stopped by order of President Jewett in July, 1882. Early in that month, the Buffalo Creek Railroad decided to make extensive improvements, such as double-tracking, rearranging grades, building new iron bridges in place of the old wooden ones, etc., and Mr. Haven was appointed Engineer in charge of construction. Other work was the building of a coal-loading trestle, for shipping coal by lake, which fronted on the City Ship Canal, and an extensive shore protection to prevent the erosion of the Company's land by the waves of Lake Erie. On the completion of the work, on November 1st, 1884, he resigned.

Then, in partnership with S. T. M. B. Kielland, M. Am. Soc. C. E., he opened an office for the private practice of engineering and land surveying. Much of his work consisted of obtaining data in relation to grants, to railroad corporations, of lands and rights in streets and other public property, as well as the boundaries of certain waterways, most of this work having been done formerly by Mr. Peter Emsley, for many years a most reliable and expert surveyor in Buffalo. It was necessary to read the "Proceedings" of the Common Council of Buffalo, and consult the old maps and other records of the City Clerk and the County Clerk of Erie County. Mr. Kielland looked after the maps and Mr. Haven read the 34 volumes of proceedings. In the meanwhile, they were engaged in surveying and various engineering employments along the Niagara River and the Buffalo docks. The partnership was dissolved in 1885, Mr. Haven remaining in Buffalo a year longer. In March, 1886, he received an appointment from the late Gen. Adna Anderson, M. Am. Soc. C. E., Chief Engineer of the Northern Pacific Railroad, and removed to Montana. In the summer of 1886 he was in charge of location and construction on the Helena and Red Mountain Railroad, and his jurisdiction was subsequently extended over the Helena, Boulder Valley and Butte Railroad, the Marysville Branch, Elkhorn Branch, Drummond and Phillipsburg Branch, and others of the Northern Pacific lines in Montana, all mountain roads in the mining regions, generally requiring skilful location and the solution of many difficult engineering problems.

Mr. Haven had a painful and trying experience in 1887, when on a visit to Buffalo. He was stopping at the Richmond Hotel, when, on the morning of March 17th, it was completely destroyed by fire. He was awakened by the electric bell in his room, on the third floor, and, hearing cries of "fire", took up his clothes and ran. He fell over a body at the foot of the stairs on the second floor, but picked himself up and rushed for the balcony, from which he was rescued by firemen. He was burned severely, especially about the feet, legs, and head, lay helpless for thirteen weeks, and was then taken to Eastern Massachusetts, to the home of his sisters (his father died in 1856, his mother in 1879, and the old home in Portsmouth was gone), thence to Cape Ann, where new cuticle was formed and his health was restored.

As the Northern Pacific Railroad Company, according to its charter, could not build branches until its main line was completed to Tacoma, it organized the Northern Pacific and Montana Railroad Company, of which Mr. Haven, on his return to Montana, was appointed Engineer, on June 21st, 1888. In this capacity he directed the partial location and construction of two important branches, the Butte line of the Northern Pacific Railroad, from Logan to Butte, 70 miles, crossing the main range of the Rocky Mountains and forming a second and alternate line between Logan and Garrison; also the Cœur d'Alêne line,

from near Missoula Point to the mining region of the same name in Idaho. The latter was about 120 miles long, and included a very difficult crossing of the Bitter Root Mountains.

In beginning the Montana surveys, Mr. Haven asked Gen. Anderson, "How steep a grade can we use on these branch lines, and how sharp a curve?" The reply almost staggered him, after being used to the maximum 0.5% grade and 4° curves on the Erie Railroad. Nevertheless, a 4% grade and a 22° curve had to be used on the Boulder-Elkhorn line.

Mr. Haven found it difficult to get locating engineers who could make grade-line surveys, and was getting impatient, when he discovered that E. H. McHenry, M. Am. Soc. C. E., one of his assistants, could do the work. This was the beginning of the career of Mr. McHenry, who succeeded Mr. Haven, and was afterward Chief Engineer of the Northern Pacific Railroad.

On May 13th, 1890, Mr. Haven was appointed Superintending Engineer of the West Gallatin Irrigation Company, in charge of the canals of the company in the valley of the West Gallatin River, in Gallatin County, Mont., which comprised about 150 miles.

Following this engagement, Mr. Haven, during 1893-95, was Chief Engineer of a railroad, promoted by Mr. Richard Harlow, planned to run from Helena, through White's Gulch to White Sulphur Springs, and probably farther east. This line was graded from Helena to near Canyon Ferry, but was never completed.

In writing of railroad building in Montana, before and after 1887, John J. Donovan, M. Am. Soc. C. E., says:

"E. H. Beckler, what a world of reminiscence his name arouses? He in charge of the Montana Central Railway, later the Great Northern, I for the Northern Pacific. Both lines under construction through the same canyons to Butte, crossing in the field, fighting in the Courts, yet with no bad blood between the two corps of engineers. Then, when finally Helena welcomed the advent of the Montana Central, we of the Northern Pacific decorated our office with the rest, hung out a big banner across the front: 'N. P. Pay your money. Take your choice. M. C.', and cheered James J. Hill and Col. Broadwater as they passed. Their hats went up in acknowledgment and they passed on. So we built for our companies and kept faith without loss of friendship."

The Montana Society of Civil Engineers was organized in Helena, on July 5th, 1887, with forty-eight charter members. Col. Joseph T. Dodge was the first President. Mr. Haven was the seventh President, filling first the unexpired term of Col. Walter W. De Lacy, and held the office during 1893 and 1894. From the time that he became President he was active in holding the Society together. During his presidency he adopted the unique system of naming but one member on a committee, claiming that one member would secure better and

quicker results than a combination. Mr. James S. Keerl, who was President in 1895, writes of Mr. Haven:

"He was a most genial companion, a gentleman of the old school, and a most entertaining and instructive talker. He was the life of the Society's meetings, and never missed one where it was at all possible for him to attend. He took a lively interest in all classes of engineering, and delighted in discussing any question of engineering presented. The Society owes him a most grateful appreciation for his sterling loyalty and for his earnest work given freely at all times in its behalf, and during the years of its infancy when it needed it most, and those who knew him best enjoyed a deep sense of gratification through his early enrollment among the Honorary Members of the Society."

It may be opportune to state here that Mr. Sigismund Low, the writer's father, was in Helena in 1871, where he had charge of the location of the Northern Pacific Railroad in Montana, under the late W. Milnor Roberts, Past-President, Am. Soc. C. E., Chief Engineer.

During 1886 and part of 1887, the late William H. Kennedy, M. Am. Soc. C. E., was an Assistant Engineer of the Northern Pacific Railroad under Gen. Anderson, engaged on location work through the Prickly Pear Canyon and Boulder Valley.

Mr. Haven was one of the early members in the first organization of Storer Post No. 1, G. A. R., of Portsmouth, N. H., and in 1889 became a comrade of Wadsworth Post No. 3, Department of Montana. He was Quartermaster of Wadsworth Post from 1892 to 1896, inclusive.

In the spring of 1896, Mr. Haven, finding it necessary for climatic reasons to leave Montana, returned to the lower altitude of Buffalo, N. Y. William F. Merrill, M. Am. Soc. C. E., who in 1870 had been one of his Assistant Engineers, was then Vice-President of the Erie Railroad, and appointed Mr. Haven Inspecting Engineer, to look after the interests of that company in connection with the elimination of grade crossings of various streets in Buffalo. In this work other railroads also joined, the whole being done under the direction of the Grade Crossings Commission. He also acted as Engineering Expert in law cases in which the Erie Railroad Company was involved. He retained his connection with this railroad until his death.

When Mr. Haven returned to Buffalo he became greatly interested in the Engineers' Society of Western New York, and was its President for several years, which included 1901, when the Society held its convention at Niagara Falls.

Owing to the marked attention accorded by him to distinguished visitors from Chile to the Pan American Exposition during that year, he was elected on November 27th, 1901, a Corresponding Member of the Instituto de Ingenieros de Chile, Santiago, Chile.

The following concerning this appointment is taken from the *Buffalo Evening News* of March 8th, 1902:

"President William A. Haven of the Engineers' Society of Western New York and Mr. George A. Ricker of that Society, have been elected members of the 'Institute of Engineers of the Republic of Chile.' Word of this honor to two distinguished Buffalo engineers was received in this city from South America yesterday, and it is understood that this action was taken by the famous Chilean National Engineering Association in recognition of the courtesies shown to visiting engineers of South America by the Engineers' Society of Buffalo during the continuance of the Pan American exposition.

"Mr. Haven, as president of the local association, and Mr. Ricker, as chairman of the Reception Committee, during the Exposition season came in personal contact with several widely known South American engineers and the visitors were much delighted with the arrangements made by the Engineers' Society of Western New York for the entertainment of strangers who were members of the profession.

"They expressed their gratification with a warmth characteristic of their race and it is evident that the memories carried back with them were cordial ones.

"Among the distinguished visitors from Chile was Senor Santiago Sotomayor, who is engaged in a tour of the world in the interests of his government, collecting information for a report on electric railways. Senor Sotomayor is a son of Gen. Sotomayor who was commander-in-chief of the Chilean forces in the recent war with Peru. He was particularly impressed with the electrical progress of Buffalo and Niagara Falls, as well as most appreciative of the courtesies extended to him, and it is believed that the honor bestowed on the Buffalo engineers and the society they represent has come through the suggestion of Senor Sotomayor."

On December 27th, 1870, Mr. Haven was married to Zaidee B. Hartupee, the youngest daughter of Dr. Andrew W. Hartupee, of Chicago, Ill. They had no children.

While in Montana Mr. Haven was a member and one of the Trustees of the First Unitarian Society of Helena.

Many engineers who were assistants of Mr. Haven became prominent later: the late James Edmund Childs, M. Am. Soc. C. E., became President of the New York, Ontario and Western Railroad; the late Robert Lewis Harris, M. Am. Soc. C. E., became Vice-President of the Erie Railroad and later President of the Northern Pacific and Chicago, Burlington and Quincy Railroads; William Fessenden Merrill, M. Am. Soc. C. E., became Vice-President of the Erie Railroad; Edwin Harrison McHenry, M. Am. Soc. C. E., became Chief Engineer of the Northern Pacific Railroad; the late Charles Latimer, M. Am. Soc. C. E., became Chief Engineer of the Atlantic and Great Western Railroad (New York, Pennsylvania and Ohio), and the late William Edwin Hoyt, M. Am. Soc. C. E., became Chief Engineer of the Buffalo, Rochester and Pittsburgh Railway, and there were many others.

Mr. Haven's natural intelligence, and his long experience and association with prominent engineers, contributed to make him a very

interesting personage. He was a veritable "treasure trove" on matters connected with the development of railroad construction and science.

In manners, he was well bred, refined, and still simple. He had a keen sense of humor, and his love for young people was a marked trait; for them he always had kind words and cheer.

His whole life, his actions, his works, and his thoughts were full of the "nobility of his soul." He hated shams and pretense, encouraged all elevating influences, was an honor and pride, and a good example to his race, to his nation, and to his profession. Those who knew him well are the better for having known him.

Mr. Haven was elected a Member of the American Society of Civil Engineers on March 5th, 1873.

ARTHUR HAVILAND, M. Am. Soc. C. E.*

DIED JUNE 18TH, 1919.

Arthur Haviland was born at Brooklyn, N. Y., on March 8th, 1848. He was the son of Daniel G. Haviland and Hannah Haviland, who were members of the Society of Friends. His father was one of the originators of Limoges china.

Mr. Haviland received his early education in France and England, and, on his return to the United States, entered Haverford College, at Haverford, Pa., from which he was graduated with the degree of A. B., in 1865.

He began his work as an Engineer in 1869, as Rodman with the San Francisco and Humboldt Bay Railroad, on surveys and construction. From 1869 until 1886, he was engaged on the various phases of railroad engineering—preliminary surveys, location, and construction—in different parts of the United States, including the preliminary and location surveys and maps of the Tehuantepec Interoceanic Railroad and the surveys of the Bar and Harbor of Coatzacoalcos. In 1885 and 1886, Mr. Haviland was employed by Mr. J. D. Crimmins (then President of the Park Board of New York City) as Engineer on his contracting work in New York City.

Leaving the employ of Mr. Crimmins, Mr. Haviland entered the office of the City Engineer at San Antonio, Tex., and, in November, 1886, was promoted to be Assistant City Engineer. In 1887, he returned to New York City on leave to be married.

At this time he accepted a position with the New York Central Railroad Company, in the service of which he remained until his death. While with this Company, he had a prominent part in the depression of the Harlem Division Tracks, between Mott Haven and Woodlawn. Following the completion of this work, he became connected with the Law and Land and Tax Departments, where he pursued lines of work that were of importance and value, and, in that connection, his death will prove to be a severe loss to the Company.

In the course of his work he formed a wide acquaintance with the contents of most of the offices of public records in New York State, and with the public officials attached thereto. He testified as witness for the Company in practically all its important lawsuits, and became known to the judges and the attorneys for his probity, accuracy, and reliance.

Since his marriage, Mr. Haviland had resided in the Borough of the Bronx, New York City, and interested himself locally in many social and civic affairs. He was a member of St. Edmund's Protestant Episcopal Church, and had been deeply interested in all the activities

* Memoir prepared by Henry Vier, Esq., New York City.

connected therewith, having served as a member and Clerk of the Vestry and as one of its Wardens. The large memorial window in the front of the church was presented by Mr. Haviland.

He was always of a cheerful and optimistic disposition, and his loss will be deeply felt by all those who were associated with him intimately, both in business and social life. He is survived by his wife.

Mr. Haviland was elected a Junior of the American Society of Civil Engineers on January 4th, 1882, and a Member on January 4th, 1888.

JOHN VOSE HAZEN, M. Am. Soc. C. E.*

DIED OCTOBER 2D, 1919.

John Vose Hazen was born at Royalston, Mass., on November 22d, 1850. Later, the family resided in Atkinson, N. H., and he was prepared for college at Atkinson Academy. He was graduated from the Chandler Scientific Department (as it was then known), in 1875 with the degree of B. S., and from the Thayer School of Civil Engineering in 1876, with the C. E. degree. The College gave him the A. M. degree in 1908.

From September to December, 1876, Mr. Hazen was employed as Rodman on the Manchester and Keene Railroad, and then served as Principal of the High School at Hancock, N. H., until April, 1877. From April to July, 1877, he was Draftsman for the Boston Bridge Works, and from August, 1877, to July, 1878, Principal of Atkinson Academy. From September, 1878, he served for two years as Tutor in Mathematics and Surveying in the Chandler Scientific School, and then as Professor of Civil Engineering and Mechanics until 1894. From that time until 1911, he was Woodman Professor of Civil Engineering and Graphics in the Scientific Department of Dartmouth College, as re-organized, and also Professor of Civil Engineering in the Thayer School of Civil Engineering.

In the summer season of 1881, Professor Hazen was engaged for three months on a survey of the Connecticut River, at Sumner's Falls, Plainfield, N. H., for a proposed dam. In the summer of 1891, he acted as Chief of Party on the survey of the preliminary line and location of the Hoosac Tunnel and Wilmington (Vt.) Railroad. In the summer of 1900, he was engaged as Chief of Party, for three months, conducting a survey for a proposed electric railroad from Ely Station, Vt., to the Copperfield Mines, in the interest of the late George Westinghouse, M. Am. Soc. C. E., who then owned the copper mines.

From 1900 to 1910, Professor Hazen served as Chairman of the Board of Commissioners of the Village Precinct of Hanover, N. H. He devoted himself diligently to the duties of this office which afforded small emolument and little thanks. He designed and supervised the construction of sewers and drains, and gave much attention to the construction of better roads, building short stretches of good macadam roadway and improving those parts most liable to deterioration. In 1909-10, he was engaged as Expert in the design and layout for an extensive coal-tar-concrete street pavement, in Lebanon, N. H. In 1910, he served his town as Expert in the grading of, and also super-

* Memoir prepared by Robert Fletcher, M. Am. Soc. C. E.

vised the construction of that part of, the New Hampshire State Highway, "West Side Trunk Line", within the town limits. Professor Hazen was always particularly interested in road construction, and labored to secure the passage, by the New Hampshire Legislature, of a general law to establish a State Highway Department which would control road construction throughout the State, thus giving a more efficient and economical administration. The advent of the automobile hastened the result which he so much desired. During the last twenty years, he did considerable expert surveying in Court cases. Being rather modest and undemonstrative in manner, many did not appreciate his ability; but those who consulted him on professional questions found him well-informed, well acquainted with sources of information, and ready to apply his knowledge to the case at hand.

In 1889, Professor Hazen attended the joint conventions of the American Societies of Civil and Mechanical Engineers, the Institution of Civil Engineers, and the French Society of Engineers, in London and Paris. He afterward traveled for a few weeks in Switzerland and England.

As a teacher, Professor Hazen was painstaking and faithful, and had the high respect and regard of his students. He was more particularly interested in descriptive geometry, railroad surveying, highway construction, and foundations. At a time when the means of pictorial presentation of his subjects were not as available as at present, he prepared many large-scale drawings and diagrams to elucidate his lectures and classroom demonstrations. During many years, he directed the preliminary course in Surveying given to Juniors in the College. At the same time, he had charge of the Railroad Surveying and instruction in Railroad Construction given to the first-year class in the Thayer School of Civil Engineering. If all the lines which he projected had been built, Hanover would be a great "railroad center". Among the young men of his classes, Professor Hazen's "stride" was proverbial. In the routine field work few could get over more ground than he, so rapidly, and with, apparently, so little effort. The railroad surveys occupied entire days, the parties taking along their lunches, and it was a rare man who, at the end of the day, would show so little evidence of fatigue as Professor Hazen. There were few, if any, instructors or professors who conducted more class work than he. There were times when he spent from 28 to 30 hours per week in the classroom, including some two-hour exercises and work with students of the Thayer School. Sometimes, with very large classes, he had to get along without as much help from assistants as he would have wished. However, he seldom grumbled, although he was overburdened, but often said that, at the worst, professors and most of the instructors in college have an easy life, free from much of the anxiety and hard

toil which is the lot of the average man. Always ready for duty, he cheerfully accepted the tasks which came to him, and accomplished what some would have regarded as much more than his share.

Professor Hazen died at his home in Hanover, on October 2d, 1919, after suffering from a disability which had gradually increased from early in the summer. He was so well known to successive classes of students through more than 40 years that his passing beyond must awaken the deep sympathy of many who will share in the grief of his family and immediate colleagues.

Professor Hazen was married to Miss Harriet A. Hurlbut, of Hanover, N. H., and his family of two sons and two daughters exemplified the best ideals of home life and neighborly relations. They have, in the recollections of his accomplished lifework, an abiding and precious heritage. He was a member and a regular attendant of the Congregational Church. He had been a member of the School Board for eighteen years, and Treasurer of the Dartmouth Religious Society for many years. Professor Hazen set an example of unflagging devotion to duty and readiness to discharge every responsibility as a citizen, exemplifying the familiar maxim of Smeaton: "The abilities of the individual are a debt due to the common stock of public well being". He had many friends and no enemies, and has left a memory to be cherished by his family and his neighbors.

Professor Hazen was elected an Associate of the American Society of Civil Engineers on June 5th, 1889, and a Member on May 2d, 1911.

GEORGE BLAGDEN HAZLEHURST, M. Am. Soc. C. E.*

DIED NOVEMBER 27TH, 1919.

George Blagden Hazlehurst, the son of Henry R. Hazlehurst and Elizabeth (McKim) Hazlehurst, was born at Baltimore, Md., on November 28th, 1855. He received his education at St. Clement's School, Ellicott City, Md., at Trinity College, Hartford, Conn., and at the University of Virginia where he studied engineering.

After leaving college in 1877, Mr. Hazlehurst was engaged by the Vulcan Iron Works of Baltimore, Md., as Draftsman, Inspector, etc., on shop work on engines, boilers, bridges, etc., and remained with this company until 1881.

In 1881, he entered the employ of the Baltimore and Ohio Railroad Company, serving successively, as Rodman, Topographer, and in charge of a party on preliminary surveys and location until 1882; as Resident Engineer on the Valley Railroad Extension, from Staunton to Lexington, Va., in 1882 and 1883; as Assistant to the Consulting Engineer of the Company in the design and preparation of bridge plans, from 1883 to 1886; as Assistant Engineer in charge of the design and construction of bridges, from 1886 to 1889; and as General Superintendent of Motive Power from 1889 to 1896.

In 1897, Mr. Hazlehurst engaged in private practice as a Consulting Engineer at Baltimore and Catonsville, Md., until 1915, when he was obliged to retire from active work on account of ill health. He died at his home in Catonsville, Md., on November 27th, 1919, after a long illness.

He was married on October 15th, 1890, to Charlotte Gill, of Baltimore, Md., who, with a son and a daughter, survives him.

Mr. Hazlehurst was a man of great reserve and dignity, with most courteous manners. He was always kind and fair to those under him and was held in great respect by all with whom he came in contact. He was a great reader and always kept in touch with current technical and general subjects.

Mr. Hazlehurst was elected a Member of the American Society of Civil Engineers on February 1st, 1888.

* Memoir prepared from information on file at the Headquarters of the Society.

JAMES NISBET HAZLEHURST, M. Am. Soc. C. E.*

DIED FEBRUARY 9TH, 1919.

James Nisbet Hazlehurst was born at Sparta, Ga., on January 15th, 1864. His father, George Hall Hazlehurst, served as a Colonel of Engineers in the Civil War, and was the owner of the Chattanooga Water-Works, and also Chief Engineer of the Macon and Brunswick Railway.

James Nisbet Hazlehurst received his education in the public schools and at Kirkwood Military Academy, and studied civil engineering for two years at the University of the South, at Sewanee, Tenn.

In 1878, at the age of 14, the boy was employed as a Rodman on the extension of the Memphis and Charleston Railway. In 1879, he was engaged, in the same capacity, on surveys for the Texas and Pacific Railway and on the construction of the New Orleans Pacific Railway. In the spring of 1880, he was promoted to the position of Assistant Resident Engineer of the Shreveport Division of the New Orleans Pacific Railway, and in the summer and fall of that year and the winter of 1881, he served as Assistant Engineer and Division Superintendent on the construction of that road from Bayou La Fourche to Provençal, La.

Later in 1881, Mr. Hazlehurst was employed as Assistant Engineer and Superintendent for A. J. Lane and Company, Contractors, on the construction of 120 miles of the Pensacola and Atlantic Railway. In 1882 he went to the New Orleans and Mississippi Valley Railway as Superintendent in charge of the extension from Vicksburg to Port Gibson, Miss., and from Baton Rouge, La., to the Mississippi State Line. He spent the fall and winter of 1884-85 as a student at the "School of Design", in Cincinnati, Ohio, and, from 1885 to 1887, was General Manager of the Lookout Iron Works and Director of the Lookout Water Company, Chattanooga, Tenn., as well as of the Montgomery Water-Works, Montgomery, Ala.

In 1887 Mr. Hazlehurst was Principal Assistant Engineer on location for the Macon and Dublin Railway, but, in 1888, he engaged in private practice as senior member of the engineering firm of Hazlehurst and Hendricks, at Macon, Ga. In 1890 he returned to railway engineering as Chief Engineer on location and construction, and, later, as General Superintendent and Engineer, of the St. Augustine and North Beach Railroad. During 1892 and 1893 he acted as Receiver for the Macon, Ga., Brewing Company, and, during 1893 and 1894, as General Superintendent and Treasurer of the Acme Brewing Company. At this time the Board of Public Works, of Macon, Ga., of which Mr. Hazlehurst was a Charter Member, was organized.

* Memoir prepared by Park A. Dallis, M. Am. Soc. C. E.

In the fall of 1894, he was employed as Constructing Engineer by Gaboury and Noble, Contractors, on sewers for Macon, Ga., and retained that position until the spring of 1895, when he again engaged in the private practice of engineering as the senior member of the firm of Hazlehurst and Company, General Contractors and Engineers, with offices at Atlanta, Ga. This firm contracted for all the sewer work done in Atlanta in 1895, and constructed the sewers and water mains for the Atlanta International and Cotton Exposition. Mr. Hazlehurst also acted during 1896 and 1897 as Consulting Engineer on the design and construction of water systems for Clarksville, Tenn., New Orleans and Algiers, La., Morristown, Tenn., St. Augustine, Fla., Forsyth, Ga., Grenada, Miss., Dyersburg, Tenn., and Hazlehurst, Miss. He also acted as Consulting Engineer to Parrott, Paterson and Company.

In the winter of 1897, Mr. Hazlehurst was appointed Acting City Engineer of St. Augustine, Fla., and completed the water-works of that city and paved most of its streets. In 1898 he was appointed Chief Engineer of the Board of Public Works of Tampa, Fla. In this capacity he located and constructed a complete system of sewers, grading, pavements, and other public improvements. He also served as City Engineer of Tampa.

In 1900 he went to New Orleans, La., as Chief Engineer of the Miles Salt Company, but, in 1901, he removed to Mobile, Ala., where he was appointed Chief Engineer of the Board of Public Works, which position he retained for five years. In 1906 he returned to Atlanta, Ga., opened an office as a Consulting Engineer, and became prominently identified with the engineering activities of that city. He was widely known throughout the South, through his connection as Consulting Engineer for many cities, among which were La Grange, Ga., Raleigh, and Wilmington, N. C., Miami, Key West, Lakeland, and Dunnellon, Fla., and Mobile, Ala. He also made appraisals of water-works for Macon, Ga., Raleigh, N. C., Chattanooga, Tenn., Ocala, Fla., etc.

When the United States entered the World War, Mr. Hazlehurst immediately offered his services to the Government. He was commissioned a Major of Engineers on June 20th, 1917, and assigned to the staff of Maj.-Gen. Leonard Wood, U. S. A., Commander of the Department of the Southeast, as Officer in charge of the Water Supply Section for the camps in the Southeastern States. In September, 1917, Maj. Hazlehurst, with other engineers, was ordered overseas in response to Gen. Pershing's request for expert engineers, and was made Principal Assistant to the officer in charge of the Water Supply Section of the American Expeditionary Forces at Chaumont, France. Later, he was attached to the Third British Army, as an observer in the Valley of the Somme, and was afterward transferred to Tours as Principal

Assistant to the officer in charge of the Water Supply Section of the American forces at that place.

In October, 1918, Maj. Hazlehurst was ordered to the South of France, as Engineer Officer in charge of construction and as Water Supply Officer for Army Base No. 6, his territory extending from the Riviera to the Italian frontier. Later, he was transferred to Paris as a member of the American Peace Commission, and was assigned to the Economical and Financial Section of the Belgian Commission, the duty of which was to study and check the damage due to the German occupation. Maj. Hazlehurst's particular studies were mines, metallurgy, railways, and industrial and general buildings, and he was made Director of the Division having to do with damages to buildings in Brussels, Belgium. While on this duty he was taken ill and died in that city on February 9th, 1919.

Maj. Hazlehurst was one of the foremost engineers of the South, and was prominently identified with the engineering activities of Chattanooga, Tenn., and Atlanta, Ga. As a resident of the latter city, he took a leading part in the organization of the Affiliated Technical Societies of that place, the first organization of its kind in the United States. He also served as Chairman of the Committee on Engineering and Good Roads of the Atlanta Chamber of Commerce, was a member of the Commission which selected the site of Camp Gordon as a military cantonment, and a member of the National Council of Defense. Maj. Hazlehurst was also a member of the American Waterworks Association and the American Public Health Association. He had written a number of articles for various technical publications and was the author of a book entitled, "Towers and Tanks."

He was married in 1886 to Miss Mary Griffiss, of Chattanooga, Tenn., who, with two sons, George Hall Hazlehurst, Sanitary Engineer of the State of Alabama, Montgomery, Ala., and Capt. John G. Hazlehurst, U. S. A., survives him.

Mr. Hazlehurst was elected a Member of the American Society of Civil Engineers on October 4th, 1899. He was a Charter Member and the first Chairman of the Executive Committee of the Atlanta Association of Members of the American Society of Civil Engineers.

JOHN GIBSON HENDRIE, M. Am. Soc. C. E.*

DIED JUNE 18TH, 1919.

John Gibson Hendrie, the son of Daniel and Jessie Gibson Hendrie, was born on December 17th, 1881, at Philadelphia, Pa.

He received his early education in Philadelphia, attending the Central High School from 1897 to 1901. He entered the University of Pennsylvania in 1902, where he took a four-year course in Civil Engineering, which he completed in June, 1906.

Mr. Hendrie gained his early experience as a Civil Engineer, with the Trussed Concrete Steel Company, the Pennsylvania Railroad Company, Franklin and Clarke, and McCormick and Company, respectively. For the last-mentioned firm, he acted as Resident Engineer in charge of the engineering work on the construction of the Mulberry Street Bridge at Harrisburg, Pa.

He served as Engineer for Weeks and Sanville until 1911, when he went with the Barber Asphalt Paving Company, and was located at Maurer, N. J., in charge of construction work until 1913. Mr. Hendrie was then sent to Brighton, Trinidad, as Engineer in charge of the Asphalt Works at that place. He returned to Maurer in 1916, and remained there until he resigned to enter the Engineers Corps of the Army.

He was commissioned a Captain in the Reserve Corps on August 15th, 1917, and served with that rank from September, 1917, until July 30th, 1918, when he was commissioned a Major.

Maj. Hendrie served in France until he was detached and ordered back to the United States to assist in the training and development of a new battalion of Engineers. He resigned from the service in December, 1918, and went to Fort Worth, Tex., as Engineer with the Pierce Oil Corporation, where he remained until his death on June 18th, 1919.

Of Scotch descent, Maj. Hendrie inherited the best Scottish traits and characteristics. He was very active in football, rowing, and other undergraduate activities during his high school and college courses. He was a member of the Phi Delta Theta Fraternity and was elected Cane Man of his class in college.

He was married on April 26th, 1913, to Maria Elizabeth Roessler, of Perth Amboy, N. J., who, with three children—Donald, Elizabeth Roessler, and John Gibson—survives him.

Maj. Hendrie was elected a Junior of the American Society of Civil Engineers on September 5th, 1911, an Associate Member on April 2d, 1913, and a Member on May 12th, 1919.

* Memoir prepared by George A. Huggins, Esq., Philadelphia, Pa.

HENRY WILSON HODGE, M. Am. Soc. C. E.*

DIED DECEMBER 21ST, 1919.

When a man passes into the next life, leaving behind him a record of high accomplishment, the World seeks for the causes that lifted him above the general level of his fellows and in so doing gives first place to those influences that play so large a part in the moulding of man's character and in the shaping of his destiny—heritage and family tradition, early training and environment, education, and the associations of later years.

In the life of Henry Wilson Hodge the effect of these influences was manifest to a remarkable degree, in cultivating the qualities that won for him lasting fame, not only as a brilliant engineer, but in an equal degree as a patriotic citizen, a loyal friend, and a fearless man of broad humanities and lofty ideals to which he was ever true.

Henry Wilson Hodge was born in Washington, D. C., on April 14th, 1865—the day made memorable by the assassination of President Lincoln—of a long line of American ancestry reaching back to early Colonial times.

His father, John Ledyard Hodge, a great-grandson of the first of the line in America, who came from Ireland about 1745, was born in Philadelphia, Pa., was graduated from Princeton, and removed to Washington at the time that his father, William Ledyard Hodge, was made Assistant Secretary of the Treasury during the administration of President Fillmore. The paternal grandmother of Col. Hodge was Sarah Bayard, of Philadelphia, whose grandfather, John Bayard, was a leading man in that city and as Colonel of a Philadelphia regiment during the Revolutionary War served in many actions and was personally complimented by Gen. Washington for his gallantry at the Battle of Princeton. This John Bayard was a great-grandson of Peter Bayard, who came to this country in 1647 with his uncle, Peter Stuyvesant, the last Dutch Governor of New Amsterdam.

The mother of Col. Hodge was Susan Savage Wilson, a daughter of Henry Parke Custis Wilson, of Virginia, and a sister of the eminent surgeon of that name in Baltimore, Md. This family, which was of Scotch-Irish extraction, settled in America in 1700 and was instrumental in founding the first Presbyterian Church in this country at Rehoboth, Md. Mrs. Hodge was a deeply religious woman of noble character, and her son often remarked to his friends that, raised as he was under Spartan conditions with no surplus of worldly possessions,

* Memoir prepared by the following committee: W. J. Wilgus, Frederic A Molitor, Howard C. Baird, and Robert Giles, Members, Am. Soc. C. E.

it was to her teachings and example that he owed the best in his character.

In fact, it is hard to imagine how Mr. Hodge could have been otherwise than a man of high principle, with such fine traditions, early training, and environment.

Educated at Young's Private School in Washington, his health, always delicate as a child, broke under the strain of untiring study, and at the age of fifteen he joined a surveying party on the Chesapeake and Ohio Railroad in the mountains of West Virginia, and carried a chain for nearly two years. The experiences of this rough outdoor life not only built up his constitution, but awakened in him the ambition to become an engineer. Acting on this thought he borrowed the necessary money through the kindness of a relative, and, in 1882, entered Rensselaer Polytechnic Institute, from which he was graduated in 1885.

Now fairly launched in his life's work, Mr. Hodge entered the service of the Phœnix Bridge Company, with which for six years, under the direction of its Chief Engineer, the late A. Bonzano, M. Am. Soc. C. E., he was successively Draftsman and Computer, Assistant Engineer and Resident Engineer, gaining through practical experience the broad foundation on which was reared his future success. Among the structures with the design of which he was connected during this period was the Huntington Bridge at Cincinnati, Ohio. He also had much to do with the planning and erection of the Pecos Valley Viaduct of the Southern Pacific Railway.

In 1891 came an important change in his fortunes when he accepted the position as Chief Engineer of the Union Iron Works, at New York City, in which city he spent the remainder of his life.

About this time Mr. Hodge joined the University Place Presbyterian Church and shortly after became an Elder and, later, one of its Trustees, giving freely of his time and substance to a cause which was always dear to him. For nearly thirty years, he was Superintendent of the Sunday-school of this Church, which he attended with unfailing regularity and where he exerted a great influence over hundreds of young people.

Soon after coming to New York City he had joined the Seventh Regiment of the National Guard. A stranger in the city, he found his service in Company K a real pleasure, and the friendships which he made there were among the warmest of his life. He always regarded his old regiment with genuine affection.

An important step in his life came in 1893 when his employment with the Union Iron Works was terminated, and he ventured into the field of the independent consulting engineer. For the ensuing two years Mr. Hodge did much important work, one instance of which was

the preparation of standard plans of bridges, of lengths ranging from 10 up to 200 ft., for the 900-mile extensions of the Choctaw, Oklahoma and Gulf Railroad, of which Frederic Molitor, M. Am. Soc. C. E., was then Chief Engineer.

In 1895 he entered the employ of the late Alfred P. Boller, M. Am. Soc. C. E., with whom four years later he entered into partnership under the firm name of Boller and Hodge, afterward changed, through the admission of Howard C. Baird, M. Am. Soc. C. E., to Boller, Hodge and Baird. Following the death of Mr. Boller in 1912, the firm name was changed to Hodge and Baird.

During this period of a quarter of a century the work for which Mr. Hodge was largely responsible covered a wide field, embracing noteworthy structures in many parts of the world. Among these were the sightly Great Northern Railroad Bridge, at Duluth, Minn.; the Choctaw, Oklahoma and Gulf Railroad Bridge, at Little Rock, Ark., the pleasing design of which stands as a monument to his instinct for good taste; all bridges for the National Railroad Company of Mexico and for several South American companies, among which were the Brazil, Cerro de Pasco, Bolivian Central, and Madeira-Mamoré Railways; all bridges for the Philippine Railways and Manila Railway; the Riverside Viaduct at 96th Street and the Melrose Avenue Viaduct, in New York City; the bridges over the Connecticut River at Saybrook and East Haddam; and all bridges for the Wabash-Pittsburg Terminal Company, including the impressive cantilever bridges of that company over the Ohio and Monongahela Rivers, the latter having a span of 812 ft., which was the longest railroad span then in existence with the exception of the Forth Bridge. His crowning work was the great Municipal Bridge over the Mississippi River, at St. Louis, Mo., in which his initiative was notably displayed in the use of nickel steel for the main members of the exceptionally long simple channel spans.

In an advisory or consulting capacity Mr. Hodge's genius was utilized on the Blackwell's Island and Manhattan East River Bridges of the City of New York; the rehabilitation of the elevated lines of the Brooklyn Rapid Transit Company; the rebuilding of the Quebec Bridge after the collapse of the original structure; the Singer and Metropolitan Towers, in New York City; and studies and investigations for the proposed great interstate bridge over the North River at New York City. He was, at the time of his death, a member of the Board of Consulting Engineers for the proposed vehicular tunnel under the North River, between Lower Manhattan and Jersey City, N. J.

It is not only by this multitude of examples of his engineering skill that the professional work of Mr. Hodge is to be judged. Never seeking office, it was with reluctance that he consented, through a sense of duty and at great personal sacrifice, to accept a place on the Public

Service Commission of the New York District proffered to him by Governor Whitman in January, 1916. His peculiar function as a Commissioner was to supervise the construction of the great subway extensions then in progress, as well as to deal with many matters of a regulatory nature. In this trying place he revealed fearlessness and powers of decision which won for him the renewed admiration of his friends and the respect and support of his colleagues, the press, and the community at large. His remarkable success as a Commissioner went far to support the claim that the engineer of character, experience, and administrative capacity is ideally suited for high public office.

The entry of the United States into the World War brought a ready response from Mr. Hodge, who sometime before had patriotically volunteered for and received a commission in the Engineer Officers' Reserve Corps. Governor Whitman felt that the subway situation in New York City was such that Mr. Hodge owed his first duty to the State, but, later, he withdrew his opposition to and accepted the resignation of Mr. Hodge, who sailed for France with the rank of Major, in July, 1917.

From this time until his discharge Col. Hodge rendered notable service to his country, first in charge of the design of railroad structures for the rapidly expanding transportation needs of the Army in France, then as Manager of Roads, and, finally, as Assistant Chief Engineer of the Army in charge of military bridges. He was promoted to the rank of Lieutenant-Colonel on October 26th, 1917, and to Colonel on August 13th, 1918, and received his honorable discharge on January 22d, 1919, soon after his return to the United States.

In the months that followed Col. Hodge entered vigorously into the rebuilding of his professional practice, but his friends noticed a change for the worse in his physical condition, beyond doubt brought about by his experiences in the Army. His sudden death, however, on December 21st, 1919, came as an unexpected shock to them.

Col. Hodge was a man of commanding figure, tall and well proportioned, with features that reflected a rare combination of strength and kindliness. His manners were always courteous and marked with the frankness and sincerity that command confidence and respect. Humor to an unusual degree was inherent in his nature and smoothed not only his own path through life but also the rugged roads of his friends, who never looked to him in vain for warm sympathy and helpful advice. To quote the words of Tennyson he was:

> "That tower of strength
> Which stood four-square to all the winds that blew."

Mentally, spiritually, physically, he truly was a man of mark, loved for his warm humanity and lofty ideals, admired for his commanding

ability and strength of purpose, and respected for his straight thinking, sterling integrity, and fidelity to duty.

Col. Hodge was married on December 14th, 1897, to Sarah Cunningham Mills, only child of George Mills, of Savannah, Ga., who survives him.

He was a Trustee of Rensselaer Polytechnic Institute, from which he received the degree of Doctor of Engineering in 1918, a member of the Council of New York University, a Director of Princeton Theological Seminary, and a Director of the American Church in Paris. He was also a member of the Board of Foreign Missions of the Presbyterian Church and of the Board of Managers of the Knickerbocker Hospital of New York City, and a Governor of "Chester Crest", Mount Vernon, a home for intemperate men.

In his profession, he was a member of the American Institute of Consulting Engineers, in which he was a Past Director, the Canadian Society of Civil Engineers and the Institution of Civil Engineers of Great Britain. He was also a Veteran of the Seventh Regiment, and Secretary of the Associates of the Engineer Corps of Company K, Seventh Regiment, National Guard, New York; a member of the Citizens' Union of New York City; and a member of the Chamber of Commerce of the State of New York. His clubs were the Century, University, and Downtown of New York City.

Col. Hodge was elected a Junior of the American Society of Civil Engineers on January 5th, 1887, and a Member on October 2d, 1895. He served as a Director of the Society from 1913 to 1915, inclusive.

FRANK CHURCHILL HORN, M. Am. Soc. C. E.*

DIED FEBRUARY 16TH, 1919.

Frank Churchill Horn, the son of Adam E. and Martha P. Horn, was born at Macomb, Ill., on January 8th, 1861. He was educated in the public schools and under private instructors.

His first engineering engagement, after acquiring some experience as assistant to an engineer in private practice, was in 1882 as Assistant Engineer on the construction of the St. Louis and San Francisco Railroad in Western Arkansas. In 1884, he was engaged as Assistant Engineer on railway location, in Iowa, Minnesota, and Dakota, for the Burlington, Cedar Rapids, and Northern Railway.

From 1885 to 1889, Mr. Horn was Principal Assistant Engineer, and, later, Chief Engineer and Superintendent, of the Department of Public Works of Lake, Ill. During this period he remodeled and enlarged the sewerage and water-works systems, besides making many other improvements in the town.

From 1889 to 1894, he served as Engineer and Superintendent for a number of contracting firms in the construction of water-works and sewerage systems in Indiana, Alabama, Ohio, and Illinois, and also for the construction of the Intramural Railway for the World's Columbian Exposition at Chicago.

In the autumn of 1894 he was engaged by the Lake Shore and Michigan Southern Railway on track elevation in Chicago. In 1895 he was employed by the Sanitary District of Chicago to construct the regulating works of the Chicago Drainage Canal at Lockport, Ill., and, again, in 1898-99, he was placed in charge of building masonry structures and bridges on the Drainage Canal. In 1900 he was employed by the Economy Light and Power Company on the construction of the hydro-electric plant at Joliet, Ill.

In September, 1900, Mr. Horn came to Idaho as Assistant Chief Engineer on the construction of the Swan Falls Hydro-Electric Plant on Snake River. On the completion of this work in 1901, he became Resident Engineer of the Denver Union Water Company, of Denver, Colo., in charge of the construction of the Platte River Canyon filtration plant and afterward of the Lake Cheesman Dam which forms a reservoir for the storage of the Platte River water for the City of Denver.

In 1905 Mr. Horn was appointed Construction Engineer in the United States Reclamation Service, and came to Idaho as Construction Engineer, first for the Minidoka rock-fill dam on Snake River, then

* Memoir prepared by A. J. Wiley, M. Am. Soc. C. E.

for the Boise River concrete diversion dam and the Upper and Lower Deer Flat earth-fill embankments.

Resigning from the Reclamation Service in 1908, he became Construction Engineer for the Salmon River Dam of the Twin Falls Salmon River Land and Water Company, near Twin Falls, Idaho. On the completion of this work in 1911, Mr. Horn opened an office in Boise, Idaho, as Consulting Engineer, and continued in this practice for the remainder of his life. In connection with the lining of the tunnels at the Salmon River Dam, he invented a process for the pneumatic conveyance and placing of concrete and devoted much of his energy to developing this process and putting it in commercial use. Among the most successful examples of its application were the lining of the Port Richmond and Stockton Street Tunnels in San Francisco.

Mr. Horn's most prominent characteristic as an engineer was the uncompromising thoroughness of his work. This was shown very strongly on the Lake Cheesman Dam, which is one of the very few, if not the only, rubble masonry dam which, from its first construction, was entirely free from any trace of seepage or sweating.

From his early experience in contracting, he acquired a taste for the personal conduct of construction work, and was always a strong advocate of force-account construction as opposed to contracting for the work under his charge. The Upper Deer Flat Embankment of the Deer Flat Reservoir of the United States Reclamation Service in Idaho is an earth dam containing more than 1 000 000 cu. yd. This dam was built by Mr. Horn with Government forces and equipment at a saving of more than $100 000 below the lowest bid. The Salmon River Dam, containing about 150 000 cu. yd. of concrete and 3 600 ft. of outlet tunnel, was also done under his direction by force account at a very low cost. He was an expert in all classes of construction machinery, and was employed by the United States Reclamation Service as Consulting Engineer in the selection of the construction equipment for the Arrowrock Dam in Idaho.

Mr. Horn was intensely loyal to his associates, and had their unqualified confidence, affection, and respect. He was an unselfish and devoted friend, and few men stood higher in the community where he spent the last years of his life. Though not a college graduate, he was elected a member of the University Club of Boise, and was its Vice-President at the time of his death. He was very much interested in questions of public health and, at one time, paid the hospital fees for the public school children of Boise, whose circumstances would otherwise have prevented them from having a necessary operation.

He was married on June 24th, 1888, to Margaret K. Ferguson, of Guelph, Ont., Canada, who died in 1899, leaving no children. His

intense devotion to the memory of his wife was one of the most touching of his many noble and lovable traits.

He died in Boise, as the result of a stroke of apoplexy, on February 16th, 1919. He is survived by a sister and two brothers, and leaves many friends and associates among whom his memory will always be cherished.

Mr. Horn was elected a Member of the American Society of Civil Engineers on September 1st, 1903.

RUFUS CAMERON HUNT, M. Am. Soc. C. E.*

DIED FEBRUARY 18TH, 1919.

Rufus Cameron Hunt was born at Bowling Green, Ky., on December 1st, 1851. His father was a farmer and long a resident of the State. His early education was obtained at a local school kept by a Professor Shields. Without the advantage of a college education, he taught himself the rudiments of engineering and began his life's work in railway location and construction—a great field, but one from which only the efficient rise to prominence or a competence.

In 1898 Mr. Hunt was a Division Engineer on the construction of a railway in Maine without apparent prospects, but his careful, conscientious work had attracted the attention of those who are always on the lookout for capable men. In that year the Bryce Syndicate was organized, under the name of the American China Development Company, for the construction of railways in China, and Mr. Hunt was offered a position as Assistant Engineer. Later, he was made Locating Engineer, and had charge of the survey from Hankow to Canton, 750 miles. Part of the line has been constructed, as laid out by him. He remained in China for some time as Chief Engineer. From China, Mr. Hunt went to Europe, and thence for more than a year to South America where he had charge of important work in the Andes Mountains and Peru. His next field was Mexico.

In the meanwhile, the subway in New York City was under construction, and the contractor who had charge of the Fort Washington Tunnel, from 160th to 196th Streets, had become so much involved that the bonding company had to take over the work. As the result of a conference between the Company, the General Contractor, and the Chief Engineer of the Commission, Mr. Hunt was selected to take charge of this highly important and difficult section. So well did he carry out his trust, that Mr. John B. McDonald subsequently placed him in charge of the Jerome Park Reservoir contract. Then followed other large pieces of contract work, but, on their completion, Mr. Hunt decided to retire from the field where he had succeeded so well and take up the life of his forefathers, that of a country gentleman. To this end, he acquired an extensive farm near Washington Court House, in Fayette County, Ohio, with which he had the same success as he had building railways or digging tunnels. He died at his home on February 18th, 1919, of pneumonia following an attack of influenza. He is survived by his widow, who was Miss Lida Saxton.

His character was like his mind and frame, rugged and strong. It was marked by a rare combination of firmness and justice, but, if any

* Memoir prepared by William Barclay Parsons, M. Am. Soc. C. E.

one quality predominated, it was unwavering loyalty. He loved truth, hated shams, and was a fine specimen of a real American. These qualities endeared him to all. As an engineer he had sound judgment which, combined with his personal traits, made him a real leader of men.

Mr. Hunt was elected a Member of the American Society of Civil Engineers on October 5th, 1904.

LINN MURDOCH HUNTINGTON, M. Am. Soc. C. E.*

DIED NOVEMBER 24TH, 1919.

Linn Murdoch Huntington was born on November 11th, 1884, at North Bend, Nebr., and was descended from old New England stock. He was graduated in Civil Engineering from the University of Nebraska in 1904, having spent all his vacations in railroad work.

After his graduation, Mr. Huntington went almost immediately to the Panama Canal and spent practically the remainder of his life in the tropics. During his three years in Panama, he rose rapidly from Rodman to Assistant Superintendent of Public Works and Assistant Engineer of Maintenance of the Panama Railroad. Transferred to Cuba during the Second Intervention, at the request of Governor Magoon, he became Second Engineer in the Department of Public Works and, later, was engaged in consulting work with Marx and Windsor, an American contracting firm.

Leaving Cuba in 1910 Mr. Huntington joined the Department of Public Works of the Dominican Republic, which he served most faithfully and creditably in many capacities until 1913, when nearly all the American employees were precipitately discharged from the service.

Shortly afterward, in 1914, he became Vice-President and General Manager of the Bramon Estates Company, which owned and operated one of the largest coffee plantations in Venezuela, where he remained until a few months before his death. It was while on this work that his wonderful persistence and splendid loyalty showed to its best advantage. For more than a year he stayed on, fighting an unequal battle for the retention of the property fraudulently taken over by German interests, though he received no salary and little support from his principals at home.

Mr. Huntington was a pre-eminent example of the fighting American engineer who has had such a strong influence in every land where the empire builder has followed the explorer into the out-of-the-way places of the earth. He might have been the inspiration of the "Soldier of Fortune" which has enticed so many of his kind to the land of the *dolce far niente*.

"Hunt" was a typical "soldier", fighting and working incessantly, never quitting, neither stopping nor giving up till the job was done, whatever it might be. Obstacles added zest to the work, but he never dreamed of failure. At the end it was the same; though suffering from a disease of the throat which had prevented him from taking even water and having been kept alive for several days with oxygen, he gave no sign that he despaired of recovery. As far as any one could see, he considered that his prospects were of the brightest, and his plans were

* Memoir prepared by John L. Mann, M. Am. Soc. C. E.

all for the future. He died on November 24th, 1919, and is survived by his widow and a son.

Having spent practically all his professional life in the tropics, Mr. Huntington had absorbed the atmosphere of the Latin American and spoke the language so well that he was frequently taken for a native of various South American countries.

He was a member of the National Arts and Salmagundi Clubs of New York City, and was the author of several short stories published by Harper's and other magazines.

Mr. Huntington was elected a Junior of the American Society of Civil Engineers on May 2d, 1905, an Associate Member on August 31st, 1909, and a Member on December 31st, 1913.

CHARLES MATTATHIAS JACOBS, M. Am. Soc. C. E.*

DIED SEPTEMBER 7TH, 1919.

Charles Mattathias Jacobs was born at Hull, Yorkshire, England, on June 8th, 1850, and died at his home at Laugharne, South Wales, on September 7th, 1919.

He was the ninth in a family of fourteen born to Bethel and Esther Jacobs. His father was a member of a family long established in Hull, a well known and highly honored merchant of that city.

Mr. Jacobs was educated by private tuition and, in 1866, at the age of 16, was articled as a pupil in the arts of mechanical and structural engineering with Messrs. Charles and William Earle, one of the leading ship and engine building firms on the northeast coast of England. With this firm Mr. Jacobs served his five-year term of apprenticeship, obtaining a thorough knowledge of all the trades involved in ship and engine building, as well as in the design of engines and structures.

This pupilage in practical work was then the usual British system of technical training. Throughout his long service as a professional engineer, Mr. Jacobs' practical understanding of, and his judgment in solving, engineering problems always reflected that early training.

In 1871, on the completion of his apprenticeship, he was sent by Messrs. Charles and William Earle to China to put up some bridges which they had contracted to build and erect.

On his return to England, Mr. Jacobs decided to follow the profession of a marine engineer and to that end went to sea in the Merchant Service for between two and three years, the period necessary to obtain the British Board of Trade certificate as First-Class Marine Engineer.

In 1876 he opened an office in Cardiff, South Wales, as a Consulting Engineer, specializing in marine engineering.

In this same year he married Frances H. M., daughter of the late John Fry, of Penarth, a leading colliery operator and shipowner. His widow survives him.

Soon after this, he was appointed Surveyor to Lloyd's Register of Shipping at Cardiff, and he held this office for a few years. During this period he became recognized as an expert and authority in a business in which Cardiff and Newport stood pre-eminent, namely, the briquetting and consequent utilization, of the slack coal-dust from the non-coking coals of South Wales and Monmouthshire.

On December 1st, 1885, he was elected a Member of the Institution of Civil Engineers. In 1887, Mr. Jacobs removed to London, where he opened a Consulting Engineer's office in partnership with Mr. Herbert Barringer, under the firm name of Jacobs and Barringer. This

* Memoir prepared by J. V. Davies, M. Am. Soc. C. E.

connection, which broadened the scope of his engineering work, continued until his death.

In 1888, the late Austin Corbin, who was then President of the Long Island, the Philadelphia and Reading, and the Elmira, Cortlandt and Northern Railroads, besides having wide interests in other organizations and subsidiary companies, became deeply interested in the possibility of using the culm or waste produced in the crushing and sorting of anthracite coal in the fields of the Philadelphia and Reading Coal and Iron Company. While in Europe in that year, Mr. Corbin consulted with Mr. Jacobs as to the possibilities of this development and invited him to come to the United States, which he did early in 1889. This was the beginning of the long and close association between Mr. Corbin and Mr. Jacobs, by which Mr. Jacobs became directly identified as Consulting Engineer with all the engineering problems of the various interests controlled by Mr. Corbin.

The most pressing problem at that time was that of an improved terminal for the Long Island Railroad. Mr. Jacobs took up the study of an extension of the Long Island Railroad from its terminals in Brooklyn and Long Island City. In co-operation with Samuel Rea, M. Am. Soc. C. E., of the Pennsylvania Railroad, he developed a plan for the extension of the Brooklyn lines by tunnel under the East and North Rivers, which would give passenger connection direct to the Pennsylvania Railroad Company's Jersey City terminal. One element in these studies was the removal from Atlantic Avenue, Brooklyn, of the surface tracks of the Long Island Railroad. The preliminary studies and estimates for doing this by elevating and depressing the railroad were made under the direction of Mr. Jacobs, and the work was later carried out by his partner, J. V. Davies, M. Am. Soc. C. E., as Chief Engineer to the Board for the Atlantic Avenue Improvement. This work, and the other studies made for the improvement of the Long Island Railroad, initiated Mr. Jacobs' connection with the rapid transit situation in New York City.

In 1891, Mr Jacobs opened an office as Consulting Engineer in New York City, his Chief Assistant being Mr. Davies, with whom he later entered into partnership. The company was finally organized as Jacobs and Davies, Incorporated, and continued without a break until the end of 1916, when Mr. Jacobs retired from practice in the United States.

In 1892, he undertook for the East River Gas Company the design and supervision, as Chief Engineer, of the construction of a tunnel having an internal diameter of 10 ft. 2 in. to connect the Company's plant at Ravenswood, Long Island, with the Borough of Manhattan. This tunnel starts at the foot of Webster Avenue, Long Island City, and ends at the foot of East 71st St., New York City, passing under both channels of the East River and under Blackwells Island. The work was a notable achievement for Mr. Jacobs. Soon after the tunnel had

been started, a seam of rotten rock giving direct access to the river was encountered, the contractor abandoned the work and Mr. Jacobs took it over on behalf of the Company, installed a tunneling shield, and finished it with his own forces after many and serious difficulties had been met and conquered.

This was the first tunnel to be finished under either the North or East Rivers, although others had been begun at an earlier date under both rivers. The air pressure used was very high, reaching 48 lb. per sq. in. (above the normal), and this is believed to be the first case in which extensive rock blasting was done under compressed air.

In 1895, Mr. Jacobs was appointed by the bondholders of the Company owning the then unfinished and abandoned Hudson River Tunnel at New York City, as one of a committee of three to examine and report on the condition of and possibility of finishing that work. As a result of this investigation, and after long delay in re-organizing the finances of the old concern, a new company was formed, under the presidency of Mr. William Gibbs McAdoo, known as the New York and Jersey Railroad Company, which took over the old work and carried on the enterprise. This was the nucleus about which the present Hudson and Manhattan Railway System of passenger railroad service between New York City and Jersey City has been built up and which now acts as the down-town New York distributing terminal of the Pennsylvania Railroad and also as the up-town and down-town New York terminals of the Delaware, Lackawanna and Western Railroad and the Erie Railroad.

The design and construction of this important system of tunnels across the North River and in New York City and Jersey City, involving many unprecedented problems both as regards design and execution, were carried out for the company by Mr. Jacobs as Chief Engineer, with his own designing, engineering, and construction forces. The construction of this system, as it stands to-day, was finished in 1910. By the completion of the "Old North Tunnel", begun in 1874, and dogged by persistent ill luck until Mr. Jacobs took over the work in 1902, the conquest of the North River was achieved, and Mr. Jacobs, of all his successes, always looked back with the greatest pride to the fact that on March 11th, 1904, he was the first man to have crossed, dryshod, beneath the great North River, from New Jersey to New York City. The work of tunneling the North River for this company was described by Mr. Jacobs in a paper* presented to the Institution of Civil Engineers on February 22d, 1910. For this paper, the Council of the Institution gave him its premier award, the Telford Gold Medal.

In 1898, Mr. Jacobs prepared the plans and specifications and awarded the contract for the Tredegar Dry Dock at Newport, Monmouthshire, on the western side of the River Usk. This dry dock is 708

* *Minutes of Proceedings*, Inst. C. E., Vol. CCXXXI (Paper No. 3859).

ft. long and 65 ft. wide at the entrance. It can take a ship of 12 000 tons, and is divisible in two sections by middle gates, so that two ships of 7 000 tons each can be docked at the same time. Many serious difficulties, due to the nature of the ground, were met and successfully overcome and the work* was finished in 1903.

The other great New York project with which Mr. Jacobs' name will be forever linked is that which brings into New York City the terminal of the Pennsylvania Railroad. It is impossible here to do more than mention that Mr. Jacobs was the Chief Engineer of the North River Division of this work, and thus had direct charge of the designs and construction of all that part which lies between the Terminal Station and the Western Portal of the tunnel through the Bergen Hill. The length of the Division is 14 280 ft., all in tunnel and all providing for two lines of track. The material penetrated ranged from the softest silt to the hardest trap rock, with every possible variety lying between the two. The work is described fully in papers by Messrs. Raymond, Jacobs, Noble, Gibbs, and members of the staff.†

Mr. Jacobs' own paper‡ describes fully his personal connection with this work dating from his consultation in London in 1901 with Mr. Cassatt, then the President of the Pennsylvania Railroad. This paper contains also a most interesting sketch of the events which preceded and led to the inception of this great scheme. One thing, however, must be made clear as it is only touched upon most lightly in his own account, and that is, that without the assurance given by Mr. Jacobs' invention to provide support, if such should be found necessary in the North River silt, for the structure and tracks of tunnels, by an internal bridge construction within the tunnels themselves, supported by piers or piles sunk to firm foundations, it is unlikely that the management of the Pennsylvania Railroad would have ventured on the uncertainties of building the great main line tunnels in this silt. Protracted and exhaustive tests during the construction period proved that these supports were not needed, but the value of their conception as an assurance to those who planned this bold feat cannot be over-estimated.

Both these undertakings, involving the crossing of the North River by six different tunnels, were carried out simultaneously by Mr. Jacobs between 1901 and 1910. Many of the problems were literally unprecedented, and to the pioneer solution of these Mr. Jacobs brought his ever practical viewpoint, his convincing personality, his indomitable perseverance, and the keen edge of his enthusiasm.

Many other works of large size and great difficulty have been carried out under Mr. Jacobs' general direction, among which are the following, stated more or less in chronological sequence.

---

* *Minutes of Proceedings*, Inst. C. E., Vol. CLXVII (Paper No. 3646).

† *Transactions*, Am. Soc. C. E., Vols. LXVIII and LXIX (1910).

‡ "The North River Division," *Transactions*, Am. Soc. C. E., Vol. LXVIII (1910), p. 32.

He was closely identified with the oil industry and built many oil storage installations in Great Britain and elsewhere, one of which was a pipe line for the Burmah Oil Company from Rangoon to Yenangyat. This line consists of about 270 miles of 10-in. and 30 miles of 4-in. pipe, between the wells and the seaboard, together with pumping stations and tank equipment. The surveys were made in 1902 and the installation was finished in 1908.

From 1907-11, he had charge, as Consulting Engineer to Messrs. Daydé and Pillé, Contractors, of the tube tunnels driven by shield under compressed air below the River Seine and the Place de la Concorde, in Paris.

From 1910-15, the construction of the Astoria Tunnel, 4 662 ft. long and 275 ft. below the waters of the East River, was accomplished. This tunnel is used to contain two cast-iron mains, 6 ft. in diameter, by which gas is conveyed from the plant of the Astoria Light, Heat, and Power Company to East 132d Street, The Bronx. This tunnel is 20 by 20 ft. in cross-section and gave rise to what was probably the worst problem in tunneling under normal air pressure yet presented in New York City. This work, which was designed and carried out by Mr. Jacobs' own forces, has been fully described.*

From 1910 to 1913, the construction of the Hales Bar Lock and Dam across the Tennessee River near Chattanooga, Tenn., was carried out by Mr. Jacobs' firm. In this case, in order to obtain secure foundations in a limestone rock, honeycombed with caverns and pockets, very large monolithic caissons had to be sunk under pneumatic pressure.

In 1912-13 the construction of the Laxaxalpam Aqueduct Tunnels of the Mexican Light and Power Company was completed by Mr. Jacobs' firm with its own forces after the work had been at a standstill on certain essential portions, owing to the severe physical difficulties, for more than a year. This work comprised a total length of 20 miles of tunnel in a mountainous part of the State of Puebla, Mexico, and notwithstanding serious physical difficulties, due both to the geological formations and the remote and mountainous nature of the country, was finished within the time desired.†

Mr. Jacobs' practice kept in close touch with marine work to the end, particularly in ship and engine building. He was responsible for the building of some 84 tank steamships and more than 100 cargo and other vessels.

Some of the large projects which he fathered, or with which he was connected, are the following:

The location of a railway by which the Long Island Railroad would cross by tunnel under Long Island Sound and connect with the Housatonic Railroad. This would have given a route to Boston, *via* the New

* *Transactions*, Am. Soc. C. E., Vol. LXXX (1916), p. 594.

† *Minutes of Proceedings*, Inst. C. E., Vol. CC, p. 345 (Paper No. 4123).

England Railroad, and it was thought would form a rival to the New Haven Railroad System. The absorption of the New England lines by the New Haven Company stopped this project.

At the same time, however, the contemplated scheme necessitated a suitable terminal station in New York City, on Manhattan Island, involving the crossing of the East River, with yards and a terminal adequate for the operation, not only of the local traffic of the Long Island Railroad, but also the through business of this projected line with its connections. Studies were then made as to the feasibility of a tunnel crossing in the vicinity of the existing Long Island Railroad Terminal, at Long Island City, but it then appeared that the cost of such necessary terminals in the East 34th Street district would be so high as to be prohibitive.

At this juncture, Mr. Corbin was offered by the late Dr. Thomas Rainey a franchise he held for a bridge structure to cross the East River between Ravenswood, on Long Island, and the foot of East 64th Street, New York City. After extended negotiations and investigations, this franchise was taken up by interests associated with the Long Island Railroad, and notwithstanding the withdrawal of the New England connection problem, it was considered that the plan of development was necessary to the extension of the Long Island Railroad itself, and, consequently, Mr. Jacobs was instructed to proceed with the construction of the bridge, terminal, and connections. This work was actually and actively commenced. Foundations for three main piers at the bulkhead lines of the two channels of the East River were built, and contracts for the masonry and superstructure were awarded, when the accidental death of Mr. Corbin in 1896 suspended all activities, which were never renewed. The appointment of Mr. W. H. Baldwin, Jr., as President of the Long Island Railroad, re-opened the study of the possibility of a terminal which would connect the Long Island Railroad with the Pennsylvania System, which, at that time, had in contemplation the construction of a North River Bridge entry into New York City. The later history of this development and Mr. Jacobs' connection therewith are stated in the *Transactions* of the Society.

The development of Fort Pond Bay at Montauk Point as a terminal for the trans-Atlantic steamship traffic.

The study and report for the French Government on a railway tunnel to cross the Seine near Le Havre to connect the State Railways on either bank.

The study and report for the Moscow-Kazan Railroad on the crossing by tunnel of the Volga River near Nijni-Novgorod.

The report on large reclamation projects for Bombay, India.

The reports on rapid transit development in Montreal, Que., and Toronto, Ont., Canada.

In his personal appearance, Mr. Jacobs was a man of striking presence and of a manner and poise most impressive. As an engineer he combined technical knowledge and good judgment, based on his long experience, with administrative and executive ability of the highest order. Many of his most important works were carried out without the medium of a contractor, with engineering and construction forces organized and directed by him for the owner. His courtesy and consideration to each of his numerous assistants and subordinates on the many projects he undertook during his busy life were never failing. Each of his staff felt that service under him was a valuable experience, and his magnetic personality inspired his men with loyalty and enthusiasm which bound them to him and to his work with bonds stronger than steel.

In his private life, Mr. Jacobs showed the same charming personality and magnetism. He made no enemies, but many close friends who were warmly and loyally attached to him. Writing of him, one of his old friends, a learned and honored Justice of the Supreme Court of New York, says:

"So many incidents of our long association come back to me and through all appear the cool, courageous, cheerful methods of our dead friend. He was at first a stranger in a strange land, but not for long. His ability, his knowledge of men, his courtesy and perseverance made their mark in the community. Tunnels under the rivers are common things nowadays but the pioneers had to struggle hard to make the financiers of twenty-five years ago appreciate the necessity and value of underground transit. * * * I am sorry he has gone. He made a great name for himself in his profession."

He had been a Member of the Institute of Mechanical Engineers since 1876 and a Member of the Institution of Civil Engineers since 1885. He was one of the early members of the Engineers' Club of New York, and had been a member of a number of clubs in New York City before he retired from active business there in 1916. In London, he maintained his membership in the City of London, the Royal Automobile, and the Royal Societies Clubs.

During the World War, Mr. Jacobs was very proud to have been associated with the production of ammunition and ordnance as a member of a Local Production Committee in the South Wales District.

Mr. Jacobs was an enthusiast in the development and use of motor cars. He was one of the early owners of a steam wagon and operated the various types as they appeared. In his religion he was a member of the Church of England. His home for many years before his death was "The Old Rectory House" at Wimbledon Park, near London. This was an ancient and beautiful Elizabethan house which he enlarged and modernized. During 1919, he had bought a summer home, a place called Glan-y-mor, at Laugharne in Caermarthenshire, South Wales,

which was ready for him at the beginning of September. He had only been in this house for a few days when he died as a result of cerebral hemorrhage. His last conscious thoughts were for those near and dear to him, and he left on his long journey with the same calm courage which had always been his. He was buried at St. Augustine's, in Penarth.

His loss leaves a gap which his friends and associates will not fill with his equal, and there is not one who knew him who will not remember him as an inspiring leader, a great engineer, and a thorough man.

Mr. Jacobs was elected a Member of the American Society of Civil Engineers on May 4th, 1904.

JULIUS LILIEN JACOBS, M. Am. Soc. C. E.*

DIED OCTOBER 2D, 1918.

Julius Lilien Jacobs, son of Morris and Rachel Jacobs, was born in Atlanta, Tex., on April 6th, 1882. He received his early education in the public schools of Atlanta, and obtained a First-Grade Teacher's Certificate at the early age of 13 years. He entered the University of Texas at that age, and was graduated from there in 1899 with the degree of Bachelor of Science. He remained out of school one year, and entered Cornell University in 1900, from which he was graduated with Sigma Xi honors in 1904, with the degree of Civil Engineer.

In June, 1905, he went with O. M. Leland, M. Am. Soc. C. E., Professor of Geodesy and Astronomy at Cornell University, on the Alaskan Boundary Survey for the United States Government; he returned in September of the same year. Shortly after this he was employed by the Phœnix Bridge Company, as a Designer and Draftsman, with which company he remained about six months.

From September, 1905, to the early part of 1907, Mr. Jacobs was engaged as Engineer by the Chicago and North Western Railroad Company in connection with its new road between Pierre and Rapid City, N. Dak.

In 1907 he entered the St. Louis office of James Stewart and Company, Incorporated, of New York City, General Contractors, and remained with that firm until the time of his death. He was first employed as Civil Engineer on the Missouri, Kansas and Texas Railroad Terminals at Parsons, Kans., and later was sent to Fort Worth, Tax., to erect the freight shed of that railroad. Shortly after completing this work he was sent to New Orleans, La., in connection with work which the company was constructing in that vicinity.

In November, 1908, he went to Houston, Tex., to erect the First National Bank Building in that city. While in charge of this job, as Superintendent, he obtained additional work for his company, and was made Southern Manager, offices being opened in Houston. Mr. Jacobs handled a vast quantity of construction work while there, among which were piers, bulkheads, and warehouses at Galveston and Texas City, the Galvez Hotel at Galveston, Library and educational buildings at Austin, for the University of Texas, several buildings for the Rice Institute at Houston, and also many warehouses at Houston. It afforded him much pleasure to have erected the buildings for the University of Texas, his Alma Mater.

In January, 1916, Mr. Jacobs moved to Norfolk, Va., where he secured for his company the contract to build two large merchandise

* Memoir prepared by S. S. Jacobs, Assoc. M. Am. Soc. C. E.

piers and extensive bulkhead works for the Norfolk and Western Railroad Company in that city.

During the World War activities, Government work in the vicinity of Norfolk, amounting to about $12 000 000, was carried on under his direction. This included two large concrete shipways, a reinforced concrete warehouse, office building, and shop improvements for the Newport News Shipbuilding and Dry Dock Company at Newport News, Va. He also built four large apartments at Newport News, Va., as a Housing Project for the United States Shipping Board, Emergency Fleet Corporation, piers and warehouses for the United States Army Engineers Depot, at Norfolk, Va., the Ordnance Depot at Pig Point, Va., and piers and extensive bulkhead work at the Norfolk Naval Base, for the United States Navy. Shortly before his death he secured a contract for another large pier at the Naval Base, and work on this had just been started when he passed away.

On account of the urgency of this war work, he kept in close touch with it all, was a frequent visitor to the different jobs, and at all times was familiar with the detail work. His rule was to settle questions immediately; he would never allow matters to remain unsettled for any length of time.

Mr. Jacobs was an untiring and conscientious worker, and weighed all questions with justice to both his company and its clients. He was a man of high principles and strong convictions, and always stood up for what he thought was right.

His sterling character and sense of justice to his fellow-men won him many friends, and all his co-workers were eager to please him. He was kind and philanthropic, and was ever ready to give counsel and assistance to those who needed it. Much of his time was devoted to charitable organizations, in which he took an active interest.

He was a great reader and student, and kept in touch with current news and all large engineering projects. He made a close study of the latter, and possessed a remarkable faculty for remembering details. Although only 36 years of age, he had achieved wonderful success, and was recognized as a leader among men.

Mr. Jacobs was a member of the Texas Engineering Society and the Engineers Club of St. Louis. He was elected Junior of the American Society of Civil Engineers on September 1st, 1908, an Associate Member on February 28th, 1911, and a Member on March 2d, 1915.

TIEN YOW JEME, M. Am. Soc. C. E.*

DIED APRIL 24TH, 1919.

By the death of Tien Yow Jeme, at Hankow, China, on April 24th, 1919, China lost one of her most useful engineers in the construction and development of the railways of the country. He was a pioneer among Chinese engineers and, on account of his long service with the Chinese Government railways, his position was unique, and he was credited with enjoying the complete confidence of his Government. Practically his whole life was devoted to the construction of railways, and the story of his career nearly covers the history of railway development in China. He first became a National figure in 1909, when he completed the Peking-Kalgan Railway, a line 125 miles long, through difficult mountainous country, connecting the capital of China with the historical frontier mart of Mongolia. In completing this line, he was the first Chinese engineer to build a railway without foreign help in any capacity.

Tien Yow Jeme was born in Canton, China, on April 26th, 1861, so that he was 58 years old at the time of his death; by the Chinese calendar and the Chinese method of reckoning age, he was 59 years old. His grandparents came from the Province of Anhwei, having migrated to Canton where his father was attached to a mercantile firm.

His education was acquired principally in the United States, where he went in 1872, at the early age of 11. He had studied for a short time in the Chinese Educational Mission School, at Shanghai, previous to being sent to the United States with thirty other youths, comprising the first group of students to be educated there, at the expense of the Chinese Government. During the course of four or five years, the Chinese Government sent altogether 120 students to the United States, and of that number, Mr. Jeme was about the youngest, having been a mere child when he left Shanghai. He was sent directly to New Haven, Conn., and placed in charge of an American family for training, eventually entering the New Haven High School, where he prepared for college. He was among the first of his countrymen to pass college examinations and, in 1878, he was admitted to Sheffield Scientific School of Yale University. On account of his aptitude for the sciences and for mathematics, he took the course in Civil Engineering. He was a most brilliant student in mathematics, and captured the prize in that subject in both his Freshman and Junior years. He was graduated from Sheffield with a Ph. B. degree in Civil Engineering, in 1881, at the age of 20.

The original Director of the 120 Chinese students was Dr. Yung Wing, the first Chinese to have been graduated from Yale, and, in

* Memoir prepared by J. G. Wong, Assoc. M. Am. Soc. C. E.

later years, those students came to be known as "Yung Wing boys". Out of the number, one has been a Premier, one a Cabinet Minister, one an Ambassador, and numerous others have been Railway Directors and Customs Commissioners. On the whole, they have done well, and are worthy products of American education. Intrigues on the part of the Chinese Mandarin Hu caused Dr. Yung Wing to be transferred to be Secretary of the Chinese Legation at Washington, D. C., and Mr. Hu himself became the Director. He had no knowledge of English and was not in the least in sympathy with any new ideas. He had been sent out by the Manchus to watch the activities of Dr. Yung Wing who, the Court feared, might lead the youths astray. After having served as Director for some time, he sent a lengthy memorial to the Throne to the effect that the young men were fast being foreignized, and he thought that on their return they would contaminate China and introduce new and demoralizing ideas; he, therefore, recommended their immediate recall. The result of this action brought about the recall of the 120 students in the autumn of 1881. It was with great reluctance that they returned to China, as several of them were within a few months of receiving their university degrees. Of the 120 young men, only two went home with degrees from the University; they were Mr. Jeme and his classmate at Sheffield, Owyang King, at one time Chinese Consul at San Francisco, Cal.

On their arrival at Shanghai, the students were ordered by the Government to report to the Shanghai Commissioner of Foreign Affairs, who was to distribute them to various places for further training and reform, in order to fit them for Government service. They were literally looked on as plotters, and their every movement was secretly watched by Government agents. Mr. Jeme with fifteen others was sent to the Foochow Arsenal, on the coast opposite Formosa. While at the Arsenal, he took a course in navigation in the Naval School there, and studied under a foreigner by the name of Taylor. After one year of study, he received his certificate and was immediately placed on board a cruiser in the Chinese Navy for further training to become a naval cadet. After a short period on the cruiser he was asked to return to the Arsenal as a teacher in the Naval School. Soon afterward, war with France was declared, and the French squadron began its attack on the Arsenal, causing confusion in the school. Just at this time the Viceroy of Canton requisitioned Mr. Jeme to go to Canton to build fortifications. His most notable feat while at Canton was his complete survey of the coast line which was mapped out for the first time.

After peace with France was declared, Mr. Jeme was attached to the Canton Military and Naval Academy as an Instructor, where he remained until he was called north by Wu Ting Fang, the former Chinese Minister to the United States, to join the railway service at

Tientsin. It was the opportunity for which he had been waiting, the chance to make use of what he had acquired at Yale and to practice the profession to which he had dedicated his life. Wu Ting Fang was at that time the Director of the Tientsin Railway Company.

Mr. Jeme first joined the railway service at Tientsin in 1888, and, thereafter, for 31 years, he was continuously on the payroll of at least one railway. His first appointment was as Cadet Engineer, an assistant to a Resident Engineer. The Tientsin Railway Company was being financed by a British loan, consequently, the Chief Engineer, and all the principal engineers, were Englishmen. The Chief Engineer, Mr. C. W. Kinder, was in charge of the building of a line from Tientsin, passing the Tangshan coal mines, to Shanhaikwan, a Customs outpost on the Manchurian border. The ultimate object of the British was to extend this line past Shanhaikwan to the metropolitan city of Manchuria, as well as to build a line to Peking on the other side of Tientsin, thereby giving a through connection between Peking and Mukden *via* Tientsin, the greatest commercial city in North China. In the construction of the line between Tientsin and Mukden, Mr. Jeme took an active part on both sides of Shanhaikwan. By steady work, he was promoted successively to be Resident Engineer and District Engineer, and, invariably, he was given charge of the end section, the hardest, on account of being the farthest from the base, and, consequently, the most difficult to which to get material and supplies.

At first, the line between Tientsin and Peking was not allowed to be built on account of strong opposition in the capital. It was feared by the leading officials that, with a railway connecting Tientsin with Peking, the position of the capital would be greatly weakened; besides, there was bound to be local opposition from the natives when the railway people started to build through the many ancestral graves in the country districts. It was not until Li Hung Chang came to the rescue that work on the line was started, but the condition was imposed on the engineers that the railway must not come nearer than 10 miles of the capital. Therefore, the line was built to a small unimportant town named Fengtai, about 10 miles south of Peking. Some time after the completion of the railway from Tientsin to Fengtai, Prince Kung wished to go to Tientsin, and, in making the trip, he first had to travel by his slow-moving mule-cart from Peking to Fengtai, taking nearly a whole day to cover the 10 miles. He then boarded the luxurious train and covered the remaining 81 miles in about 3 hours. The difference in speed and comfort was too great to pass unnoticed, so when the Prince returned to Peking, he lost no time in removing the restrictions which had prevented the railway from approaching the capital. It was on the extension of this 10 miles that Mr. Jeme served as Resident Engineer. Later, when the line from Tientsin to Mukden was completed, both lines radiating from Tientsin were amalgamated into

what is known to-day as the Peking-Mukden Railway. In all, Mr. Jeme was connected with the Peking-Mukden Railway for 12 years, during which time he was always on active construction work.

During the Boxer trouble in 1900, when all the northern railways had suspended work, Mr. Jeme joined the Pinghsiang-Liling Railway, as a Construction Engineer. This line was being built to develop the coal mines at Pinghsiang, Kiangsi Province, and to bring the coal to a water route in Hunan Province. The Boxers had destroyed a part of the Tientsin-Peking Line, which caused the Allied troops to occupy the railway, as an English loan was involved. However, as soon as the rising was crushed, the railway was returned to China, and Mr. Jeme was asked to go back to the north to resume his former connection with the company.

In 1901, after the Boxer movement was quelled, the Imperial Court, on its return to Peking from Sianfu, Shensi Province, decided to go to the Imperial Tombs at Hsiling for ancestral worship. On September 20th, 1901, an Imperial Edict was issued expressing the desire of the Court, and, according to the Chinese custom, an Imperial road must be built. In this case, the suggestion of a railway was adopted, and the Court appointed Mr. Kinder as Chief Engineer to survey and construct the line. The French Minister at Peking at once presented a protest against Mr. Kinder's appointment, and asked for the appointment of a French engineer, claiming that, as the proposed line was to branch out from the Peking-Hankow Railway, a French loan line, French engineers should be entrusted with the work. Both the French and the English interests used every means in their power to get the appointment for an engineer of their own nationality, but as they could not compromise, they were forced to agree to the appointment of a Chinese engineer. Mr. Jeme was the logical choice, and, accordingly, he was made Chief Engineer of the Hsiling Railway.

The controversy between the French and English had consumed much time, and only about four months remained before the date set for the Imperial worship. The trains had to be ready by February 22d, 1902, for the local officials who had charge of making the preparations for the worship. Four months to survey, build, and run trains over 28 miles of virgin country! It was in the middle of winter, when the rivers were all frozen, making transportation of material troublesome; material was scarce and difficult to transport. Old rails were borrowed from the Peking-Mukden Railway, straightened, and used for sidings; the sleepers were spaced farther apart than for ordinary practice, and the large structures were of a temporary nature. During those four months, Mr. Jeme worked about 15 hours a day, and, for many nights, he could not sleep, because he knew that if he failed to have the trains running, he undoubtedly would have to forfeit his life. It was his first trial, and was accomplished under great handicaps, but,

fortunately, he was able to satisfy the Court, and the trains were operated for the Imperial Worship. When the Imperial Court had returned safely to Peking, he was rewarded by the rank of Prefect, a great honor in those days. He was also retained to make the roadbed a permanent one. From that time, his name began to be known throughout official ranks, and he became a great favorite of Yuan Shi Kai, then Viceroy at Tientsin, who had had principal charge of the arrangements for the Imperial Worship. Mr. Jeme never forgot the men who had helped him on this work and who had made his success possible.

Mr. Jeme's next important work was in connection with the taking over of the Tao-Ching Railway by the Chinese Government. This road had been built by the Peking Syndicate, an English corporation operating coal mines in North China. The railway is a branch of the Peking-Hankow Line and taps the great anthracite coal deposits of Shansi Province. Mr. Jeme represented the Chinese Government in the valuation of this line, and, later, in 1905, the Chinese Government paid the Peking Syndicate £614 600, the valuation set by Mr. Jeme in conjunction with the General Manager of the Syndicate.

Just about the time that the Hsiling Railway was completed with a permanent roadbed, Mr. Jeme was called to Canton on account of the death of his father. While at Canton, he was asked to join a commercial railway starting at Swatow on the coast. He subsequently went to Swatow, but only stayed there about two months, when he left for Shanghai, to accept a position as Consulting Engineer to the Shanghai-Nankin Railway Administration, which position he retained for nearly a year.

After the Allied Command had handed back the Peking-Mukden Railway to China, the line did a tremendous business and had plenty of money in its treasury, after deducting all operating expenses and meeting all loan obligations. Naturally, the Director wished to make use of this surplus for the construction of more lines; consequently, he recommended the building of the Peking-Kalgan line. Friends of Mr. Kinder in the capital at once started a campaign for his appointment as Chief Engineer of the proposed line. This seemed to be a logical choice, as the money for the proposed line had come from the surplus fund of an English loan railway, and, besides, Mr. Kinder was admitted to be a capable engineer of proven ability. However, there was great disappointment among his many admirers when it became known that the Russian Minister at Peking had handed the Chinese Government a protest against his possible appointment, pointing out that China had an understanding with Russia that any railway built beyond the Great Wall toward Mongolia must be financed by Russian capital and built by Russian talent. However, if the Chinese themselves could furnish their own money and men, he had no objection. By that time, Yuan Shi Kai had become a powerful man in the Cabinet, and he took up this challenge of the Russian Minister. He at once

sought audience with the Emperor to whom he urged the building of the Peking-Kalgan line; he knew just the man who could do the work, and he recommended that Mr. Jeme be appointed Chief Engineer. Yuan had implicit faith in Mr. Jeme's ability to carry out the project, and, later, it was shown that he had not misplaced his confidence. Thus, it came about that Mr. Jeme received the appointment over his former chief for the second time. It had not been of his own seeking, for he had great respect for Mr. Kinder. It was the inevitable, brought about by the peculiar conditions in each case, for Mr. Jeme was not a man to intrigue for another man's job. Besides appointing Mr. Jeme as Chief Engineer, Yuan Shi Kai had the foresight to make him Vice-Director concurrently, thereby giving him a voice in the Administrative Department. About two years later, he was promoted to be the Director. As the Chief Engineer, Mr. Jeme personally located the line and fixed the grades, and construction began immediately.

It was in the construction of the Peking-Kalgan Railway that Mr. Jeme gave proof of his greatness as an engineer and as an administrator. He inspired his men by his own hard work, and told them that they must succeed, as the eyes of the world were watching them. He impressed on them that whether they failed or succeeded, it was not their own failure or success, but must be shared by many generations to come. There was great team work throughout the ranks, for the men realized the full significance of their undertaking; and to those builders, their Chief, and the Chinese in general, the Peking-Kalgan Railway will stand forever as a monument to their ability and efficiency, and shows what the Chinese are capable of accomplishing when the right leader is found among them.

The Peking-Kalgan Railway cost about 7 000 000 taels complete. Mr. Jeme estimated the cost of the line at 7 223 900 taels, the work to be completed in four years. In his original estimate, he requisitioned for 1 800 000 taels per year, but was given only 1 300 000 taels during the first two years. In spite of this reduction, he completed the work within the scheduled time, and 4% under his original estimate in cost. The average cost per mile was 56 000 taels, equal to about $39 200 in gold, at the rate of exchange at the time. Whatever the critics may still have to say, the fact remains that a standard in construction cost has been set by a Chinese for the Chinese Government railways. There were reasons for this low cost. First, all the Chinese engineers dealt directly with the contractors, therefore, interpreters who might cause leakages in payments from the railway office to the contractors were not necessary. Then, there was no commission to be deducted at every purchase, as is the case for all foreign loan railways when the foreign purchasing agent is allowed the commission.

After the completion of the Peking-Kalgan Railway, in 1909, Mr. Jeme was engaged to carry on the work of extension. He retained his position on this railway until the end of 1911, when the Revolution

upset all departments of the Government service. At the opening ceremonies at Peking, Mr. Jeme received a great ovation from the people. It was one of the proudest moments of his life, equalled by only two other occasions, when he was praised by Dr. Yung Wing in the presence of all his schoolmates for capturing the Sheffield Freshman Prize in Mathematics, and his grand reception at Canton, when he went there to become President of the Canton Section of the Canton-Hankow Railway. In recognition of his great work, Mr. Jeme was given the Honorary Doctorate Degree by the Government. He was also made an Adviser to the Ministry of Education and Consulting Engineer to the Ministry of Communications. In 1910, he was appointed Chairman of the Board of Civil Service Examiners, for the examination of more than 700 men who had been educated in foreign countries.

Directly after the opening of the Peking-Kalgan Railway to traffic, the Viceroy of Szechuen Province sent a petition to the Throne for the second time, asking for the release of Mr. Jeme from Peking, in order that he might take up the construction of the Szechuen Section of the Hankow-Szechuen line. As everything was running smoothly on the Peking-Kalgan Railway, Yuan Shi Kai allowed Mr. Jeme to accept the offer, but still retained him in the service of the Peking-Kalgan line. Accordingly, Mr. Jeme went to Ichang in 1909 to accept the position of Chief Engineer of the Szechuen Railway Company, a privately owned company. The Szechuen line was to start from Ichang, Hupeh Province, and was to open up the Province of Szechuen, with ultimate connection with Hankow. Ichang is a treaty port on the Yangtze River, about 1 000 miles from Shanghai, and is situated just at the mouth of the famous Yangtze Gorges. The Railway Company had previously engaged a young Chinese as its Locating Engineer. He had already spent several years in the Szechuen hills, and Mr. Jeme's part on his arrival was to start the construction of the line. Mr. Jeme did not favor the located line which went inland, away from the Yangtze River, and was, therefore, much longer than a river line. He was of the opinion that a river route was better. However, as several years had already been spent in location work, the Company would not allow any more time for further investigations. The shareholders were clamoring for results; they wanted to see trains running. The natives throughout the Province were curious to know what a railway was like, they had heard so much of its wonderful performance and yet after spending so much money and waiting for so long, there was no sign of one. In later years, whenever a party of engineers went into Szechuen Province, the natives would invariably say, "coming again"? Mr. Jeme's opinion concerning the river line was afterward confirmed by surveys made during 1913 and 1914 by American engineers under Richard Wood Randolph, M. Am. Soc. C. E., Chief Engineer of the Szechuen Section of the Canton-Hankow-Szechuen Railways. In 1911, the Szechuen Railway Company was taken over by the Govern-

ment and this action was one of the chief causes of the Chinese Revolution. After the Revolution, the two trunk lines—Hankow to Canton, and Hankow to Szechuen—were amalgamated into one system to be financed by the so-called Group Bankers Loan, composed of British, French, German, and American capital, and the Szechuen line, now known as the American Section, was given over to the Americans as their field of activity.

In 1910, while he was at Ichang, busy getting construction work started, Mr. Jeme was informed that he had been elected President of the Canton Section of the Canton-Hankow line, a privately owned railway, even to this day. After construction at Ichang was under way, Mr. Jeme left for Canton to take up his newly added duties. In order to save money for the Company, he also acted as its Chief Engineer. He had been Consulting Engineer to the Lock-Tung Railway since 1909, so that during 1910 and the greater part of 1911, he was holding six different positions concurrently on four different railways. His time was spent between Peking, Ichang, and Canton.

When the Revolution broke out in 1911, Mr. Jeme was devoting his energies to the extension of the railway at Canton, and the Revolution gave him the chance to prove his faithfulness as its custodian. There was great excitement in and around Canton during the early period of the Revolution. Everybody who could afford it went to Hong Kong for protection under the British flag, but Mr. Jeme remained on the job. His staff threatened to desert him, and his many friends advised him not to take any chances by remaining in Canton. He called together the various chiefs of each department of the railway, and told them that he was going to stick to his post, but that if any one among them was afraid to stay, he could go; however, before they left, everything must be handed over to him or his representative in perfect order. In the end, nobody left, the trains were kept running throughout the Revolution, and the railway did not suffer in any way. A neighboring railway was looted after its Director and principal heads had deserted the place at the first sign of trouble. Everything that could be carried off was taken, and it was rumored that the remaining staff, mostly of the lower class, looted the railway themselves.

With the abdication of the Manchus, the country was somewhat restored to order, and the Canton-Hankow-Szechuen Railways System was organized. President Yuan Shi Kai sent a delegate to Canton to bring Mr. Jeme to the capital for appointment as Associate Director-General of the System. He was especially charged by Yuan to look after the technical part of the railway administration at Hankow. At the beginning the Director-General's post was reserved as a pension for some Revolutionary hero. It was passed from hand to hand during the first year, and, finally, a politician got the job, but only retained it for about six months when he died. Yuan then ap-

pointed Mr. Jeme as Director-General, the date of the appointment having been June, 1914, and from that time until his death, he retained this position. While he was Director-General, on the British Section, the portion between Wuchang and Changsha was completed and opened to traffic; on the German Section, a roadbed was completed for 164 km., but the tracks had been laid for only a short distance when the war stopped further work; on the American Section, no construction was attempted.

Besides the honors already mentioned, Mr. Jeme was appointed to represent China on the Allied Technical Board at Harbin. In 1916, he received the LL. D. degree from the British Colonial University at Hong Kong. He was Chairman of the Technical Committee in the Ministry of Communications, Vice-Chairman of the National Communications Conference, Honorable Member of the Board on Railway Laws and Regulations, Member of the National Transportation Committee, and he was twice decorated by the Chinese Republican Government. In 1916, on the thirty-fifth anniversary of his Class, his Alma Mater offered him the honorary degree of M. A., but he was unable to go to the United States to receive it.

During the construction of the large bridge across the Yellow River, on the Tientsin-Pukow Railway, the work was held up by the local gentry who demanded the addition of more spans. The natives drove off the German engineers and the German contractors and refused to let them proceed with the work. The Director was in despair, as he was unable to cope with the situation. He asked for help from the Government, and Mr. Jeme was sent to investigate and commissioned to do what he could to settle the matter. He not only explained everything satisfactorily to the gentry, but also secured their consent to quarry rubble from a near-by hill, thereby cheapening the cost of rubble. In this mission which required tact and diplomacy, he saved the Government many thousands of dollars.

He was the first to introduce the use of rack-a-rock in China during the construction of the Peking-Kalgan Railway. On every railway of which he had charge, he set a high standard in pay for the Chinese engineers. He believed firmly that Chinese engineers should receive the same pay as European engineers of the same rank and for the same work. He had a warm place in his heart for young engineers, especially for those who had been educated abroad. To them he was an inspiration, and was always looked to for guidance. He was always accommodating to any one who sought his help.

The following story is a concrete example of his silent fight for the good of Chinese engineers. While he was still Associate Director-General, the German Chief Engineer, Mr. Linow, sent an official communication to the Director-General for sanction to send for a number of German engineers of all ranks to replace the Chinese engineers.

Mr. Linow said in his letter that "the Chinese engineers were no good" Mr. Jeme was aroused at once by this letter and strongly advised the Director-General that under no consideration must such an application be sanctioned. He clearly saw that if this was allowed, it would create a precedent for the wholesale importation of foreign engineers and likely to be followed by other foreign loan railways. In time, Chinese engineers would disappear from the railway service. The Director-General not wishing to get himself into trouble with the Germans, wired from Peking that the Associate Director-General would have the power to decide the question. Accordingly, Mr. Linow was asked to come to the Director-General's office for consultation. On his arrival, he was asked to re-read his letter to see if it was correct. Mr. Linow replied that the letter was quite correct. Then Mr. Jeme asked him what he meant by the statement, "Chinese engineers were no good". Mr. Linow replied that he only meant those whom he had who were not up to the standard. Whereupon, Mr. Jeme gave the letter back to Mr. Linow and told him that the statement was too broad, he must alter that letter. If, however, Mr. Linow thought the Chinese engineers whom he had were not up to the standard, better ones would be found until he was satisfied. Mr. Jeme also told him that if any Chinese engineers were dismissed, the vacancy must be filled by Chinese according to the loan agreements. He also expressed the opinion that he did not believe it would be just for any foreign loan railway to import foreign engineers to fill all the ranks; it was all right for experienced foreign engineers to take the principal positions, but the lower ranks ought to be reserved for the Chinese to get the practice and training. In the end, Mr. Linow saw the justice of Mr. Jeme's refusal, and acted accordingly. This was one of many such cases, where Mr. Jeme took the burden on his own shoulders for the good of the Chinese in general.

As time goes on, Mr. Jeme's record of achievements will undoubtedly receive greater recognition. He was always a clear thinker and a man of few words. In his long years of toil, he was never known to have made an error in judgment, and although a man of strong convictions, he was always open to argument and ready to receive suggestions and give them consideration. He was never known to fail in keeping a promise, and was always punctual at his office, at meetings, or at social functions. Between him and those who were with him through his early struggles, there existed a deep and sincere affection. To the older class of Chinese engineers, he was always their leader, one to whom they always went for advice and help. He was frank, open in his dealings, honest to the core, and above petty personal interests. He was a true gentleman at all times, courteous to all, and possessed of high moral conceptions.

He was a man of the most simple tastes, modest in the extreme, and never harbored resentments or belittled those who opposed him; he was never jealous of the man above him. He always considered himself as an engineer, and never mixed in politics. When the Revolutionary party asked him to join their ranks, he refused politely saying that he was only an engineer, one who was to make progress by his creative and constructive endeavors. He was one of the founders of the Chinese Institute of Engineers, and obtained its recognition by President Li Yuan Hung. It was his aim to give the Society a standing that would qualify its members to accept any technical post under the Government. Through his efforts, several thousand dollars have been collected toward a building fund for the Society, and Mr. Jeme secured temporary quarters in Peking for it. Whenever he was in Peking, he always stayed at the Society headquarters in preference to the luxurious hotels.

He was a lover of the American game of baseball and, on his return trip in 1881, he played on the All-Chinese team organized by the returning students. The All-Chinese team played an exhibition game with an Oakland semi-professional team and surprised the Americans by their excellent playing. He took a keen interest in the Yale ball team and followed its history through his alumni papers. He was enthusiastic over tennis, and occasionally played a set or two with his children. He lived a clean life, and had never known sickness until about a year ago, when he was first attacked with dysentery from which attack he never fully recovered. During the past year, his health began to fail rapidly, but he stayed at his work, hoping all the time that he would soon be well again. He was in poor physical condition when President Hsü sent him to Harbin to represent China on the Allied Technical Board. The long journey and the strain of the work had their telling effect, for three days after his return to Hankow on a short leave, he was advised to enter the hospital for careful treatment.

On his arrival at Hankow, he had decided to request President Hsü to release him from all public duties, and had asked his Secretary to prepare his resignation, which he had just time to initial, when he passed away at the hospital. According to the doctor who attended him, his death was due to heart failure and overwork.

In his valedictory petition to the President, Mr. Jeme urged the training of more engineers, with every chance for practice, recommended the appointment of a competent expert to succeed himself on the Allied Technical Board, and, finally, the speedy completion of the Canton-Hankow-Szechuen Railways, especially the Szechuen line, on the great future of which all engineers, travelers, writers, merchants, and missionaries have agreed.

On his death, President Hsü issued a mandate in which he commanded the National Historian Committee to record Mr. Jeme's deeds in the history of the Nation, donated the sum of $2 000 toward defraying the funeral expenses, and ordered the Civil Governor of Hupeh Province to represent the Government at the funeral services at Hankow in offering sacrifices. Mr. Jeme's many friends at Canton, Shanghai, Tientsin, Hankow, and Peking held memorial services to pay him tribute.

Mr. Jeme was elected a member of the Institution of Civil Engineers of Great Britain in 1894. He was also a member of the Royal Academy of Arts and of the Shanghai Engineering Society (Europeans), President of the Chinese Institute of Engineers, President of the Hankow Foreign Educated Men's Club, member of the Chinese Railway Association, and while at college, a member of the Alpha Phi Fraternity.

He was married in 1887, at Canton, and his widow, five sons, two daughters, one brother, and one sister survive him. His two eldest sons had only returned from the United States, in February, 1919, one having been graduated from Yale in Civil Engineering and the other from Tri-State College in Mechanical Engineering.

The following telegram and letters show in what high esteem Mr. Jeme was held by those who knew him and who had been associated with him:

The following telegram of condolence was received from the Hon. Paul S. Reinsch, the American Minister to China:

"We are greatly shocked by information of death of Dr. Jeme whose efficient services to Chinese railway development and whose eminent qualities of character gave him a distinguished position of confidence with all Americans."

John F. Stevens, M. Am. Soc. C. E., President of the Inter-Allied Technical Board, wrote as follows:

"Dr. Jeme was known to me somewhat by reputation before I had the pleasure of his acquaintance, and I am glad to believe, his friendship. During the short time I was associated with him in our work on the Allied Technical Board, I was deeply impressed by his quick grasp of any matter which we had under consideration, his rapid, and to my mind, excellent judgment.

"While a man of few words, he was decisive, and we all greatly respected his opinions, and one could readily see that, coupled with a thorough technical knowledge of railway problems, he possessed what was even more valuable, strong common sense and a thorough belief in his convictions.

"Above all, he was a gentleman, and the great pleasure I have in the memory of his association, is only equalled by the sense of loss not only personal to all of us, but a very great one to his country."

C. J. Carroll, M. Am. Soc. C. E., Chief Engineer of the American Section of the Canton-Hankow-Szechuen Railways, wrote:

"During the past two years that I have been associated with the late Dr. Jeme in affairs of the Szechuen-Hankow Railway, I have always found him deeply and personally interested in the ultimate success and completion of not only this railway, but also in a broader sense the comprehensive railway development of China.

"Dr. Jeme was recognized as the leading Civil Engineer of China on account of his technical ability, of which I had many occasions to observe, as a man of real accomplishment such as the carrying through to completion and success the Peking-Kalgan Railway, and as a man of broad ideals, interested and enthusiastic in the development of China's transportation system as a whole.

"All who came in contact with Dr. Jeme could not help but admire not only his ability as an administrator, a conceptor, and an engineer, but his interesting personality and gentlemanly instincts which inspired confidence.

"At the time of his death he was looking forward to the success of his great ideal, the opening up of Szechuen by a railway through the noted and difficult Yantze Gorges. By his death, China has suffered a great loss and I trust that further honors will be conferred upon this noted man by the nation."

The following letter was received from H. A. Raider, Assoc. M. Am. Soc. C. E., former District Engineer of the American Section of the Canton-Hankow-Szechuen Railways:

"The writer had the happy experience of having been associated professionally with Dr. Jeme Tien Yow, and expresses his deep feelings at the loss of a friend and of an engineer who had become of inestimable value to his country in the development of her numerous railway systems.

"Dr. Jeme was without doubt the ablest engineer that China has produced, and might well be called the Father of Engineering in China, because not only of having been the first Chinese Engineer to build and operate entirely with Chinese a large and difficult railway undertaking, but because he was always the first to contribute to, encourage, and maintain any society or measure that would promote the science of engineering in China.

"He was a man of great ability, possessing fine personal qualities, and commanding the good will and confidence of all his associates. He undertook with enthusiasm and characteristic attitude of duty, every assignment made him by his Government, even to his last, which was indirectly responsible for his early death.

"I trust the young engineers of China will set him up as a model, a man who followed his profession because his country needed engineers, when with his ability he might have amassed wealth in commercial life."

Mr. Jeme was elected a Member of the American Society of Civil Engineers on November 30th, 1909.

CASSIUS WILLIAM KELLY, M. Am. Soc. C. E.*

DIED DECEMBER 3D, 1918.

Cassius William Kelly, son of John Kelly and Sarah (Sigler) Kelly, was born on May 10th, 1848, in Pleasantville, Pa., where he received his early education. Later, he went to Yale College, and, unaided, worked his way through the Academic Department, and then through the Civil Engineering Course of the Sheffield Scientific School, receiving the degree of Bachelor of Arts in 1870, with a Phi Beta Kappa standing. He received the degree of Bachelor of Philosophy in 1872.

In June, 1872, Mr. Kelly entered the Engineering Department of the City of New Haven, and was connected with that department, in various capacities, for the remainder of his life—a period of forty-six years.

On January 18th, 1893, he was made City Engineer by the unanimous vote of the Board of Public Works, and served in that capacity until November, 1912, when he was made Consulting Engineer—a position for which he was eminently qualified, not only by his engineering ability, but also by his thorough knowledge of the engineering features and development of the city, and by his familiarity with the intricacies of charter provisions, contract formalities, and the legal technicalities affecting a city's structural growth.

Mr. Kelly's earlier work included a complete trigonometrical survey of the city; determining and establishing street lines and grades; complete charge of paving operations; and the charge of sewer construction during the year preceding his appointment as City Engineer.

In the design of deep masonry foundations for movable bridges he was conservative, and at the same time showed great originality in dealing with the problems involved. His designs for arch bridges of reinforced concrete were well worked out, and the finished bridges are not only adequate but also very satisfactory to the eye.

Mr. Kelly's remarkable memory, keen reasoning powers, and the acknowledged accuracy of his judgment rendered his decisions final and conclusive on many a disputed point.

In his profession, as well as in social intercourse, his absolute integrity and unvarying kindliness gained for him the love and high esteem of all who knew him.

Mr. Kelly is survived by his widow, formerly Frances E. Hart, and two daughters, Miss Miriam F. Kelly and Elsie L., wife of Mr. Grey W. Curtiss.

He was a member, and the Clerk, of the Dwight Place Congregational Church, a member of the New Haven Chamber of Commerce, and the Connecticut Society of Civil Engineers.

* Memoir prepared by Henry H. Gladding, M. Am. Soc. C. E.

Politically, he was a Republican, on general principles, but did not hesitate to exercise an independent discriminating judgment in local issues.

Mr. Kelly was elected a Junior of the American Society of Civil Engineers on March 1st, 1882, and a Member on June 6th, 1888.

PAUL SOURIN KING, M. Am. Soc. C. E.*

DIED OCTOBER 30TH, 1919.

Paul Sourin King was born at Philadelphia, Pa., on March 16th, 1845. Until he was fourteen years old, he was seriously hampered by the fact that he was crippled in both legs. As a boy he attended the public schools and, later, went to a small college in Westmoreland County, near Greensburg, Pa., but he was largely self-educated.

At the age of seventeen, Mr. King was employed by Herman Fisher, a Mining Engineer, at Ashland, Schuykill County, Pa., with whom he stayed about one year. In 1865, he was engaged as Rodman with the Locating Corps of the Mahonoy and Broad Mountain Division of the Philadelphia and Reading Railroad, under Charles E. Byers, Chief Engineer, principally on work connected with the Port Clinton, Hamburg, and Kutztown Branch, and other branches of the road, until 1870.

From 1871 to 1875, Mr. King served as Chief Engineer of the Roanoke Valley Railroad Company, on the construction of 53 miles of that line in Virginia, his headquarters during this time being at Richmond, Va.

In 1875 and 1876, he was engaged as Engineer in charge of the Virginia and Gold Hill Water-Works Extension, on the location and construction of a tunnel through the Sierra Nevada Mountains, as well as a pipe line, dams, etc., in the State of Nevada, and from 1877 to 1879, he was employed as Chief Engineer of the Union Island Reclamation Company on the location and construction of 30 miles of levee work, piling, damming sloughs, etc., in California.

In 1880, Mr. King went to Mexico as Assistant Engineer on the location of the Mountain Division of the Mexican National Railroad, and remained there until 1881. On his return to the United States, he was engaged with Messrs. Oliver Barnes and Charles McFadden, who, at that time, were grading about 30 miles of road in Elk, McClain, and Clearfield Counties in Pennsylvania. He was also employed as Division Engineer on the Pittsburgh, Youngstown, and Chicago Railroad, on the location of the Ohio River Bridge crossing, etc., in Pennsylvania.

About this time the construction of the South Pennsylvania Railroad, from Harrisburg to Pittsburgh, was under way, and Mr. King was appointed Division Engineer on the location of the road through the Blue Mountain Section in Pennsylvania.

Mr. Robert H. Sears, Chief Engineer of the Lehigh Valley Railroad, recommended Mr. King to the President of the Bethlehem Coal and Iron Company, and, in 1883, he was sent by the latter Company to Cuba as Chief Engineer of the Juragua Iron Company, Limited, Rail-

* Memoir prepared from information furnished by Henry King, Esq., and on file at the Headquarters of the Society.

road, on the location and reconstruction of 18 miles of difficult mountain road, as well as bridges and a pier for loading iron ore in the harbor of Santiago, Cuba.

On his return from Cuba in 1885, Mr. King was engaged by the Lehigh Valley Railroad Company to build a branch of that road between Buffalo and Geneva, N. Y., of which work he was Chief Engineer.

On the completion of this work, he established an office for the private practice of engineering as Consulting Engineer in New York City, which he maintained for more than 15 years. During this period, he went to South America with the editor of *Engineering News* and, in addition, traveled extensively, attending practically all the Worlds' Fairs.

Although, as has been stated, Mr. King was crippled in the early years of his life, he had recovered entirely from this condition; in fact, he frequently stated that he could outwalk any man in his party. He had never married.

To his friends Mr. King was known as a fine, noble, unselfish character—a man of scrupulous integrity and a high sense of honor—and it was this fact which brought to him important positions of responsibility and trust in engineering work.

Mr. King was elected a Member of the American Society of Civil Engineers on July 3d. 1889.

HERMANN LAUB, M. Am. Soc. C. E.*

DIED DECEMBER 10TH, 1918.

Hermann Laub, of Swiss ancestry, was born in Durmentingen, Wurtemberg, on April 14th, 1855, his family having moved there from Switzerland some years before that time.

At the age of twelve he entered the Preparatory School at Riedlingen, where, in addition to his mathematical studies, he took up English, French, and Spanish before entering the Higher Preparatory School at Biberach.

After pursuing the preparatory course at the Polytechnical School of Stuttgart for Civil Engineering, he was admitted as a full student, and was graduated as a Civil Engineer in 1879. He also pursued the course of civil engineering at the Munich Technical High School.

In 1880 Mr. Laub came to the United States, where he took a position in Denver with the Denver and Rio Grande Railroad. From 1881 to 1884 he was engaged in railroad location with the Mexican National and the Mexican Central Railroads. While connected with the Mexican National Railroad, he located a road from Salvatierra to Celaya, San Miquel, and San Luis Potosi. As Locating Engineer of the Mexican Central Railroad, he located a road from Tepic to Navaretta and San Blas, on the Pacific Coast, over some of the roughest country in Mexico. During his three years in Mexico, he located, in all, more than 500 miles of railroad.

At the conclusion of his work in that country, Mr. Laub went to Pittsburgh, Pa., where he accepted a position as Designer with the Schultz Bridge Company, in whose employ he remained from 1884 to 1887. Among the chief designs he made while with this company were those for the Junction Railway Bridge over the Allegheny River at 33d Street, Pittsburgh, the Indianapolis train-shed, and numerous other structures. In 1887 and until 1890 he associated himself with Gustav Lindenthal, M. Am. Soc. C. E., during which time the Smithfield Street Bridge and extensions were executed, and a bridge over the Monongahela River at Duquesne was built.

In 1890, Mr. Laub established himself in Pittsburgh as a Civil and Consulting Engineer, and from that time until his demise occupied and enjoyed a high place in the Engineering Profession, having always the esteem and high regard of his clients.

In 1908 he was engaged on the reconstruction of the Homeopathic Hospital, at Pittsburgh, Pa.; and in 1910 he was called upon to repair, at great risk, the 22d Street Bridge, without stopping traffic for a single day.

* Memoir prepared by A. L. Schultz, M. Am. Soc. C. E.

For many years Mr. Laub was selected by the State of Pennsylvania as Bridge Engineer for the erection of numerous bridges throughout the State. He represented more than twenty bridge companies as expert Valuation Engineer during the period from 1909 to 1916 in condemnation proceedings for the sale of bridges to Allegheny County.

Mr. Laub's versatility enabled him to design various structures for special purposes, covering almost every form of industrial plant, in addition to long-span bridges of every design over the Monongahela, Allegheny, and Ohio Rivers, such as the McKeesport and Port Vue Bridge in 1909, the Brownsville Bridge in 1913-14, the Parkersburg, W. Va., Bridge, in 1915-16, and the Norfolk Bridge in 1917-18, also, in 1914-17, the repair of the Hot Metal Bridge for the Monongahela Connecting Railroad over the Monongahela River at Pittsburgh.

Among the chief industrial plants constructed under his supervision were the Chambers-McKee Glass Plant, at Arnold, Pa.; the McKee Glass Plant, Jeanette, Pa.; the Oliver Iron and Steel Company (various mills); the galvanizing plant for the National Tube Company, the Rochester Tumbler Company, and the Federal Glass Company, at Cambridge, Ohio.

Mr. Laub was one of those generally robust, earnest, and untiring workers whose keen judgment was always gladly accepted. His general disposition showed a marked reserve, but to his intimates he displayed a lovable attitude. Mr. Laub was always in good health, so that his sudden demise from heart failure on December 10th, 1918, came as a shock to all with whom he was acquainted.

On November 27th, 1884, he was married to Miss Rosa Hauber, at Jersey City, N. J., and she, with two sons and two daughters, survives him. One son was in the service of the United States Navy at the time of his father's death.

Mr. Laub was elected a Member of the American Society of Civil Engineers on September 1st, 1897.

GEORGE STEVENS LEAVENWORTH, M. Am. Soc. C. E.*

DIED AUGUST 8TH, 1919.

George Stevens Leavenworth was born on August 17th, 1858, at Charlotte, Vt. He was graduated from the University of Vermont in 1885, with the degree of Civil Engineer.

After serving a short time with the United States Coast and Geodetic Survey, and with the City Engineer of Burlington, Vt., Mr. Leavenworth, in March, 1886, took up location and construction work on the Burlington and Missouri Railroad, the Marietta and North Georgia Railway, the Knoxville Southern Railway, and the Missouri, Kansas, and Eastern Railway.

In April, 1896, he went into street railway and hydro-electric development work, on which he was employed, chiefly in Massachusetts and New York State, until about 1901, when he returned to steam railroad construction on the Manitoulin and North Shore Railway, the Algoma Central Railway, and the extension of the Little Kanawha Railroad.

In 1903, Mr. Leavenworth resumed street and interurban railway work as Chief Engineer of the Powers and Mansfield Company, of Troy, N. Y., in which work he continued until about 1912, when he engaged in railroad and mining engineering in the South. In this connection, he was employed with the Carolina and Yadkin River Railroad and the Tennessee Copper Company, continuing in that work until his death which occurred at his home in Ducktown, Tenn., on August 8th, 1919. He is survived by his wife, who was Miss Sarah H. Smith, of Charlotte, Vt.

Mr. Leavenworth was quiet and unassuming in manner and had a lively sense of humor. He had a keen analytical mind, and his aptitude for railroad location was very great. His integrity was never questioned, and his honesty of purpose impressed all who had dealings with him. He represented fully the highest type of engineer, and all who knew him have suffered a loss by his death.

Mr. Leavenworth was elected an Associate Member of the American Society of Civil Engineers on June 3d, 1903, and a Member on February 5th, 1907.

* Memoir prepared by W. H. Mansfield, M. Am. Soc. C. E.

MAXYMILIAN LEWINSON, M. Am. Soc. C. E.*

DIED SEPTEMBER 19TH, 1915.

Maxymilian Lewinson was born in Plock, Poland, on March 14th, 1855. After he was graduated from the Polytechnicum, in Zurich, Switzerland, in 1877, where he met Professor Ruleaux and others famed for their research work in various departments of science, he entered for a short time the employ of the German State Government.

About 1880, Mr. Lewinson came to New York City and met the trials of a stranger in a strange country with courage and determination, his education being his principal asset.

After a time, he became associated as Engineer with the late Leopold Eidlitz, an architect of great ability and extensive practice. In this capacity Mr. Lewinson was called on to solve many complex problems of construction, such as the rebuilding of the Assembly Chamber roof, at Albany, N. Y., and the reconstruction of Cooper Institute.

Mr. Eidlitz, although practicing architecture, was himself well grounded in the fundamentals of engineering, which fact created the tie leading to a close friendship with Mr. Lewinson that continued to the time of Mr. Eidlitz's death.

Later, Mr. Lewinson practiced his profession on his own account, and, still later, he formed a partnership under the firm name of Baker and Lewinson, Architects and Engineers.

Under the administration of Albert F. D'Oench, Architect, then Superintendent of the Department of Buildings, he entered the employ of the City of New York. Up to this time (1888), so-called practical builders seemed to have met the needs of this Department, and the educated engineer had failed to find recognition. However, the wonderful development in building operations and the dawn of skeleton building construction in the City of New York created a demand for an engineer of ability, and Mr. Lewinson found himself, therefore, the first engineer of this important Department of the City's activities.

Toward the close of 1889 he severed his connection with the Department of Buildings, and entered business as an Engineer and Contractor for iron and steel work, especially as related to buildings.

In March, 1891, he formed a partnership with the writer to engage in general engineering practice and as contractors for structural work. This affiliation proved to be most happy, and the firm enjoyed a prosperous career until the dissolution of the partnership in 1903. Mr. Lewinson then organized the corporation of Lewinson and Company, Engineers and Contractors, and became its President, which position he retained until his untimely decease.

* Memoir prepared by the late George A. Just, M. Am. Soc. C. E.

Mr. Lewinson was a contributor to the *Transactions* of the Society, and often took part in the discussion of papers presented at its meetings.

He became a member of the Engineers Club in 1890. He was also a member of the Museum of Natural History, a Director of the Manhattan Square Apartment Association, and for a term was Highway Commissioner of the Town of Scarsdale, Westchester Co., N. Y. The latter position he accepted as a public duty, giving freely of his experience and advice for the benefit of his fellow-townsmen, he having become a resident of Scarsdale.

Mr. Lewinson was married, but left no issue. An elder brother, Simeon Lewinson, engaged in mining operations in the West, survives him, as well as relatives residing in Europe.

Mr. Lewinson was a most lovable character. He delighted to entertain his friends, and always proved an admirable host. He was generous to a fault. To any one who applied to him for assistance it was promptly and cheerfully granted. He was a well-read man, with a broad general education, and this permitted him to discuss with intelligence and force, not only important questions in engineering, but also world politics, literature, and art. In his death, his professional and social acquaintances suffered a great loss.

Mr. Lewinson was elected a Member of the American Society of Civil Engineers on February 7th, 1894.

ROBERT EMMET McMATH, M. Am. Soc. C. E.*

Died May 31st, 1918.

Robert Emmet McMath was born in Varick, Seneca County, N. Y., on April 28th, 1833. One of the vivid recollections of his childhood was going with his parents to Little Falls, N. Y., to see the first passenger train go through that place on its trip from Schenectady to Utica.

When he entered Williams College from which he was graduated in 1857, he found that he was handicapped by the deficiency of his preparatory course, particularly in the languages, as compared with men who had prepared at Andover and other Eastern schools. While at Williams, he was a fellow student of the late President James A. Garfield, through whose influence he became a member of what was known there as the Anti-Secret Society.

In the latter part of October, 1858, Mr. McMath went West and settled in St. Louis, Mo. He entered directly on the active practice of his profession, his first work having been the design and reconstruction of a levee around Columbia Bottom at the junction of the Mississippi and Missouri Rivers.

From 1859 to 1862, he served as Deputy County Surveyor of St. Louis County, Missouri. In 1862, he entered the employ of the Government as an Assistant Engineer with the United States Coast Survey, under the late Alexander Dallas Bache, Hon. M. Am. Soc. C. E., as Superintendent. While awaiting orders, Mr. McMath made a reconnaissance survey of the environs of Philadelphia, Pa., until the spring of 1864, when he was ordered to Washington, D. C., to report to Gen. Meigs, Quartermaster Corps, U. S. A., for duty. Under orders from Gen. Meigs, he made a topographical survey of Arlington Heights. This property was owned by the Lee family, but had been confiscated by the Government for use as a burial ground for soldiers dying at or near Washington, and is now known as the Arlington National Cemetery.

Early in February, 1865, Mr. McMath, with others of the Coast Survey, was ordered to Nicaragua, where the Central American Transit Company, under grant from the Nicaraguan Government, was about to make a survey for the Nicaragua Canal. On this detail, he was engaged on a survey of Greytown Harbor and about 1 000 miles of the San Juan River which at that time was bordered on each side by an unpenetrable wilderness. Until their return to New York, the members of the party had not heard of the surrender of the Confederate Army or the assassination of President Lincoln, and during the voyage

* Memoir prepared from information on file at the Headquarters of the Society.

home had been continually apprehensive of capture by a Confederate cruiser.

In the fall of 1865, he received and accepted an offer of a position as Assistant Engineer with the U. S. Engineer Corps. His first work in this capacity was on the survey of the Illinois River from La Salle, Ill., to the Mississippi River. In 1867 and 1868, he had charge of a hydrographic survey of the Illinois River, and, in 1869, he was engaged as Assistant Engineer on a survey of the Arkansas River until September, when he was placed in local charge of the improvement of the Illinois River, as part of a canal and slack-water navigation from Chicago, Ill., to the Mississippi River. It was while he was engaged on building dams in the Illinois River that Mr. McMath applied the practice of lumbermen of using brush and stakes, with such ballast as might be available, a method afterward used to a great extent in similar work on the Mississippi and other rivers.

Mr. McMath remained on the work of the improvement of the Illinois River, until July, 1872, when appropriations having been made by Congress for the improvement of the Mississippi River, he was assigned, in August, 1872, to take charge of the improvements of the harbors of St. Louis, Mo., and Alton, Ill. In April, 1873, he was appointed Principal Civil Assistant on the improvement of the Mississippi River, between the Illinois and Ohio Rivers, and, in October, 1878, he was put in charge of special physical investigations thereof. He served with the Mississippi River Commission on similar work from 1880 to 1883, when he was appointed Sewer Commissioner of St. Louis, under Mayor Ewing, which position he held until 1891.

Mr. McMath had never had any experience with sewer work prior to his appointment as Sewer Commissioner, but when the opportunity of doing important and necessary work for the city thus presented itself, he did not hesitate to accept it. During his incumbency of the office, he originated the drainage scheme for what is known as the Vandeventer District of St. Louis, which had presented problems that had been stumbling blocks of long standing to the Department. Under his direction, a complete topographical survey of the city was made, which is still referred to in planning sewer extension. He also made a special study of the question of the size of sewers required to serve large areas, and embodied the results of these studies in a paper* which was presented before the Society. The formula given in that paper for determining the expected discharge of storm water from areas exceeding 100 acres, known to engineers as the "McMath formula", was widely accepted and used by engineers throughout the country. It has been stated that, in this formula, Mr. McMath "had no idea that

* "Determination of the Size of Sewers", *Transactions*, Am. Soc. C. E., Vol. XVI (1887), p. 179.

he was contributing anything but a method to engineering science and really did not think that he did."

From 1891 to 1893, Mr. McMath was engaged in the private practice of engineering as a Consulting Engineer, in St. Louis. In April, 1893, he was nominated and elected to the office of President of the Board of Public Improvements of St. Louis, and served in that capacity until 1901. In this position he was obliged to familiarize himself with all kinds of municipal problems. He was a prominent member of the City Hall Commission, under the control of which the present City Hall was built, and this building was constructed largely along the lines suggested by Mr. McMath.

After severing his connection with the City Government in 1901, Mr. McMath engaged again in the private practice of his profession as a Consulting Engineer, retaining his office in St. Louis, until he retired a few years before his death, on May 31st, 1918, to his home in Webster Groves, Mo.

Mr. McMath was married in 1859 to Miss Frances Brodie, of Detroit, Mich.

He was a prominent member of the Engineers Club of St. Louis and had been identified with its activities almost from its organization. He served as its Vice-President in 1885, and was elected its President in 1886. He also served as Club Librarian from 1891 to 1893, and was elected an Honorary Member in 1910. The following extracts are taken from a memoir of him, prepared by Robert Moore and John A. Ockerson, Past-Presidents, Am. Soc. C. E., and M. L. Holman, M. Am. Soc. C. E., for the Club:

"While his career was marked by unusual service, this was only natural for one of his remarkable ability. His integrity was as pronounced as his professional capabilities and considered both as a man and as an engineer nowhere in contemporary history can there be found a character more worthy of emulation. Sincere, always most assiduous in his effort to reach the best solution for the problems that he was set to master, a wide reader and a ready writer, his thoroughness gave his contributions to the affairs that claimed his attention the stamp of authority and finality. As one of his associates has aptly said 'when Robert McMath gave his opinion on a subject you knew that it was the result of careful, conscientious study, enhanced by a wide experience and determined by a splendidly trained mind.'

"During the period of his association with the Mississippi River Commission, Mr. McMath was regarded as the best informed engineer on river hydraulics in the country. The elaborate reports which he compiled from time to time were considered as standard and conclusive on many of the problems pertaining to the regulation of the river."

* * * * * * *

"Personally, though a man of few words, his friendship could always be counted upon, and he was generous to the last degree, both in

the assistance he rendered his colleagues and in the aid he extended to the young men associated with him who were just growing up in the profession.

"The life of Robert McMath presents one of those rare instances where personality has embraced intellect, sensibility and will of the highest order, each happily balanced against the other and forming a character of charm and power.

"Those of us whose privilege it was to have known him cherish the memory of our association together. The State and society have been enriched by his example of uprightness and his constructive achievements."

The following paragraph is quoted from Mr. McMath's autobiography, and is a fitting close to an account of his life:

"As is the usual lot of men, I have had opportunities for usefulness, and if it has not fallen to my lot to accomplish any great work, I have lived at a time when great advances were being made in matters affecting the welfare of men of all classes and kinds. The material advances and changes have affected all classes and conditions of mankind, and the most that any of us can claim is that we have not failed to meet the responsibilities of the hour and to do what was given us as our work."

Mr. McMath was elected a Member of the American Society of Civil Engineers on March 3d, 1880. He also served as a Director of the Society in 1889.

EDGAR MARBURG, M. Am. Soc. C. E.*

DIED JUNE 27TH, 1918.

Edgar Marburg was born on March 4th, 1864, at Hamburg, Germany, where his father had sent his family from New Orleans during the Civil War. His father, Herman Edward Marburg, was a man of artistic tastes and a lover of arts, who had planned to devote himself to languages but who finally engaged in business and succeeded so well that he became a wholesale merchant. He came to America in 1847, representing a Hamburg firm, and became a naturalized citizen in 1853. His mother, Clara Juergesen Marburg, was also a native of Germany. Edgar Marburg was third in a family of four sons and two daughters, all of whom—including both parents—have survived him.

In early life, Mr. Marburg showed those characteristics of independence of thought and action that marked his later life. It is related that at the age of five years, by a series of questions which he asked his mother and by reasoning the matter out entirely by himself, he learned to tell the time.

He attended private schools in New Orleans and later in Shreveport, La., and from the beginning showed much aptitude for study, particularly for mathematics. His teacher at Shreveport, Capt. George E. Thacher, soon recognized his mathematical ability and placed him in a class by himself in that subject, with no lesson assignments. Young Marburg would simply report from time to time how far he had progressed in his study. His family have to-day a book in which he kept, in neat, orderly arrangement, solutions of many problems, from simple ones in arithmetic to those in analytic mechanics and calculus. He made it a rule never to ask or accept help on any problem, and this self-reliant attitude was evident throughout his life in everything he undertook.

At the age of fifteen he gave up school and announced his intention of going to college. It was necessary for him largely to work his way through, and he accordingly worked for the next three years in a large wholesale grocery store in Shreveport. He studied at nights to prepare to enter the sophomore class at college. On the advice of Capt. Thacher, and because of his predilection for mathematics, he decided to study Engineering and finally entered Rensselaer Polytechnic Institute in 1882 as a sophomore, at the age of eighteen. The promise of his early youth was fulfilled in his college life, and he was graduated with the degree of Civil Engineer in 1885.

Of his college days the following letters bear testimony to his activi-

* Memoir prepared by Samuel Tobias Wagner, M. Am. Soc. C. E., and Charles Laurence Warwick, Assoc. M. Am. Soc. C. E.

ties and character at that time. Enrique A. Touceda, M. Am. Soc. C. E., writes as follows:

"While he was always intensely interested in Institute happenings and was always popular with the student body, and particularly so with his classmates, he was modest and more or less retiring, having little to do with Institute politics. Without being what is known as a 'grind,' his first thought was to make good in his studies and then to devote as much time as possible to the enjoyment of general college life. During this period little if any attention was paid by any of the students to athletic sports, first due to lack of time, and second to the fact that the Institute possessed no athletic field.

"Marburg as a youth was appreciated by his associates as one of sterling worth, very interesting and very companionable. He was intellectually vigorous and quick of judgment; always dependable and ready to render a friendly service on the instant."

Palmer C. Ricketts, M. Am. Soc. C. E., President of the Institute, writes:

"Marburg, of course, was a very excellent student while here. He was graduated with the degree of Civil Engineer in the Class of 1885. He was a member of the Rensselaer Society of Engineers when a student and was the first editor of the *Institute Quarterly*, a paper which had a brief existence. * * * We all liked him when he was a student here and after he was graduated. He was a very able man, a man of fine integrity and of fine disposition."

He had definitely decided at this time to specialize in structural engineering and aimed to obtain as varied an experience as possible. Consequently, he adopted the plan of going from one bridge or structural company to another, studying at each one until he had the experience he desired. These changes were at times made at a loss of salary, but this feature never swerved him from his determination. In his later associations with young graduates, Mr. Marburg always endeavored to impress on them the importance of gaining experience in their profession and cautioned them against making increase in salary their sole consideration in changing positions.

In 1885 he entered the employ of the Keystone Bridge Company at Pittsburgh, Pa., and remained there until about 1887. The late Edwin Thacher, M. Am. Soc. C. E., who was then Chief Engineer, wrote as follows regarding this engagement:

"I was Chief Engineer of the Keystone Bridge Co. in Pittsburgh in 1885 when Mr. Marburg graduated from the Rensselaer Polytechnic Institute at Troy. He had applied for a position a month or more previously and I told him to come on if he was willing to start in at a salary of $50 per month, which was paid to all beginners. He came at the appointed time, and I set him at work on the design of plate girder bridges, at which he soon became expert. He was kept on this line of work for nearly a year, much longer than he should have been for his own good, for I believe it is the practice in all large bridge

drafting rooms to keep a man at the class of work that he is most expert in; but finally Mr. Marburg before he left did get considerable experience in the design of pin connected bridges and buildings.

"I was very favorably impressed with Mr. Marburg from the first day I saw him. His appearance and bearing were such as to satisfy me that he was a young man of superior ability, and of all the men in the drafting room he was my favorite. He had no bad habits and was a conscientious worker."

From 1887 to about 1889 he was in the service of the Phœnix Bridge Company at Phœnixville, Pa., employed almost entirely in the Computing Department of that company. From 1889 to 1900 he was with the Edgemoor Iron Company, at Wilmington, Del., in the Designing and Estimating Department under C. W. Bryan, M. Am. Soc. C. E., now Chief Engineer of the American Bridge Company.

In 1891 he returned to his home in Shreveport and it was at that time that he met and became engaged to his future wife, Miss Fanny Dulany Moncure. In 1891 and 1892 he was in the employ of the Carnegie Steel Company (Keystone Bridge Company) at Chicago, Ill., under Charles L. Strobel, M. Am. Soc. C. E., who writes as follows as to his work at that time:

"Dr. Marburg was employed by the Keystone Bridge Co. (one of the Carnegie firms), Chicago office, in 1891-92, which office was in my charge. I was at the time Consulting Engineer of the Keystone Bridge Company and of Carnegie, Phipps and Co., Limited. Dr. Marburg was engaged upon the work of preparing shop and mill plans for the structural iron work required for the large fireproof Auditorium Building, Chicago. This was unusually complicated work, as the building was designed to serve several purposes—part to be a concert, opera and convention hall, another part to be an office building and a third part to be a hotel. It was necessary to do the work under great pressure as to time, in order to permit the use of the large hall for the meeting of the National Republican Convention in the fall of 1892. Dr. Marburg was earlier employed in connection with a revised edition of the Carnegie, Phipps and Co. Handbook, then in preparation.

"Dr. Marburg's splendid qualities of conscientiousness, thoroughness, faithfulness and competency were in evidence, as they have so conspicuously been in his later life."

In 1892 a number of engineers recommended him to Dr. Charles Custis Harrison, then Provost of the University of Pennsylvania, for the position of Professor of Civil Engineering at that institution. He was elected Acting Professor of Civil Engineering and a year later became full Professor, a position which he held until his death.

Possibly no one is better qualified to speak of his qualities as a teacher than William Easby, Jr., M. Am. Soc. C. E., who was associated with him for many years at the University of Pennsylvania.

"Few have left a stronger impress of their personality on a life's work than has Edgar Marburg, for twenty-six years Professor-in-charge of the Department of Civil Engineering. Throughout this long period, covering years of devoted service, he gave unstintingly of the best that was in him toward the upbuilding of the department so wisely entrusted to his charge. That he was successful is well known and strikingly apparent to any who can compare the curriculum and facilities for instruction of a quarter of a century ago with those of the present.

"Dr. Marburg's influence on engineering was far-reaching and salutary. It was strongly felt in his work as a teacher, writer and executive throughout a wide and important circle of professional friends and acquaintances. It may truly be said that he supplied in himself, through his broad contact with Engineering, a bond between his students and the professional life which they sought to enter. Though not himself a practicing engineer, he showed in his instruction the fullest appreciation of the value of practical illustration and acquaintance with business procedure. Through patient and sound advice he endeavored at all times to instil into the minds and hearts of his students a high regard for the dignity and worth of their chosen profession. The high standard of professional ethics which he set for them was but the expression of principles which he consistently observed throughout his professional life.

"Dr. Marburg fully recognized and accepted the opportunities and obligations of his position as a teacher in a great institution of learning. With him teaching was not principally an occupation with a livelihood as its object, but a profession of the highest order which he knew to be far-reaching in its influence on the economic and social fabric of the country, worthy of that patient and devoted effort which he always bestowed upon it. His success as a teacher is unquestioned, and followed naturally from the possession of those qualities which secure the respect, confidence and interest of students. He had to an unusual extent the faculty of divesting a subject of difficulties by exposing, through familiar and often homely illustrations, the fundamental thought involved and by arranging related matters with due regard to their importance. Recitations never lagged, were never tedious or unprofitable under the vitalizing influence of his strong nature. He felt the intellectual pulse of his classes and was quick to detect lack of comprehension. It was never too much trouble to extend instruction beyond the class-room to the earnest student in need of assistance.

"A strict disciplinarian in all things essential, Professor Marburg still had the good will if not the affection of his students, based on his absolute fairness and justice and on the evident desire to apply the penalty for misdoing more as a corrective and deterrent than as a punishment. Since his death not a few letters have been received from his former students attributing much of their success to his instruction and influence as a man and expressing heartfelt regret that they had postponed the acknowledgment of their debt to him in person until too late."

The following is a copy of the resolutions of the Faculty of the Towne Scientific School of the University of Pennsylvania upon his death:

"EDGAR MARBURG, Sc. D., LL. D.,
"Professor of Civil Engineering, 1892-1918.
"Deceased June 27th, 1918.

"Moved by a profound sense of loss, this Faculty deems it a privilege to here record its estimate of the character and attainments of a colleague, who, although removed by death, has left an abiding influence for good through the vitality and idealism of his life work.

"The career of Edgar Marburg, shortened by its very excess of self-giving, nevertheless had long yielded him a distinguished position among engineers and educators. This was due to exceptional force of character and intellectual endowment which, both in preparatory training and professional and teaching activities, placed everything he did on a high plane. His work was marked by clarity and readiness of insight, grasp of essentials and thoroughness of method, and was inspired by high principles and a rugged honesty of view and purpose.

"Efficiency of so high an order, addressed to essentials, through more than thirty years of incessant activity, has made the life work of Edgar Marburg a contribution of positive constructive value to the welfare of the community. In two channels particularly has this been demonstrated; the more widely known that of the American Society for Testing Materials, whose great service to the Engineering and industrial worlds is due, more than to any other single influence, to his labors. The other channel, invisible but potent, is that of the careers of many students who have passed under his influence, carrying away as fundamental to their action his ideals of professional conduct.

"It has been well said of him that he had a constant desire to know the truth and be guided by it; possibly this best explains his life and the reason why we, his colleagues, are moved to add to this summary of his achievements an expression of profound respect for his character and of affectionate regard for the underlying warmth and kindliness of his nature.

"To the family of Professor Marburg we offer our sincere sympathy in their bereavement, and while knowing that no mere words can lessen its magnitude, we yet venture to hope that consolation may be found in the knowledge that his life, although prematurely ended, has been rich in a usefulness not to be measured by length of days.

"*Resolved:* That the foregoing be adopted as the sense of this Faculty, and spread upon the minutes, and that copies be addressed to the family of Professor Marburg and the professional organizations of which he was a member."

In 1906 a new building at the University of Pennsylvania was dedicated for the use of the Departments of Civil, Mechanical and Electrical Engineering, embodying at that time all of the latest approved facilities and apparatus required by technical schools of the highest grade. The planning and detail designing of this building was entrusted to Dr. Henry W. Spangler, at that time Professor of Mechanical and Electrical Engineering, and Dr. Marburg, who were given *carte blanche* by the Trustees. The product of their joint work will always be a monument to each. At the time of the dedication of the building

Honorary Degrees of Doctor of Science were conferred upon Professors Marburg and Spangler.

Almost immediately after settling in Philadelphia, Dr. Marburg became connected with the Engineers' Club of Philadelphia and was its President in 1900. His work in this connection is well set forth by George S. Webster, M. Am. Soc. C. E., as follows:

"In the death of Edgar Marburg, the Engineers' Club of Philadelphia lost one of its most valued members; one who always took an active interest in its welfare.

"He was elected a member of the Club October 21st, 1893, and was chosen one of the Directors in 1895 and 1896; and ably served as President during the year 1900. He was Chairman of the Committee on Public Relations in 1912, and from March 21st, 1908 until the time of his death was one of the Trustees of the Bond Redemption Fund.

"Dr. Marburg was deeply interested in the several movements of the Club to enlarge its sphere of usefulness, to increase its membership and to bring it into closer relations with other technical societies; and he contributed in no small measure to the accomplishment of the splendid results which followed these efforts.

"Earnestness of purpose and high ideals were among his characteristics, impelling him to urge the most exalted standards of ethics for the Engineering Profession, and to recommend as a duty a more active participation by Engineers in public affairs, in order that they might render greater service to the community.

"He was a man of strong convictions, and while energetically presenting his views, was very considerate of the views of others, and heartily united with them in doing that which seemed to be best for the interest of all.

"He took a leading part in making constructive suggestions at the hearings held in October, 1914, before the Engineers' Commission, appointed by the Governor of the State of Pennsylvania to investigate and report upon the advisability of licensing engineers. The clear and logical way in which arguments were presented by him at these hearings exerted a large influence upon the Commission in reaching its decision not to recommend the enactment of a License Law at that time.

"Dr. Marburg was a man of scholarly attainments, and made numerous valuable and interesting contributions to technical literature. He possessed characteristics which made him distinctive among his associates and marked him as a forceful man with original and striking ideas and quick to put them into effect. In fact, it was his unbounded energy coupled with the deep knowledge of the subjects he took hold of—and his resourcefulness in solving the problems which arose therewith—which made of him a distinguished and representative member in his profession.

"His sterling qualities and unquestioned honesty of purpose gained for him the respect and admiration of all his associates, and his death is mourned as a great personal and professional loss not only by the members of the Engineers' Club of Philadelphia but by all who had the privilege of his acquaintance."

At a meeting of the Board of Directors of the Engineers' Club held July 8th, 1918, the following resolution was adopted:

"The Engineers' Club of Philadelphia learns with profound sorrow of the death, on June 27th, 1918, of its beloved fellow-member and Past-President, Edgar Marburg. The Engineers' Club has, in the death of Edgar Marburg, lost one of its most valued members, whose loyal service has left a deep impression on the history and development of the Club, whose scholarship has earned for him an international reputation and whose personal influence has helped the members in their work and professional advancement.

"The Engineers' Club extends to his family its warmest sympathy in their bereavement and sorrow; and as an acknowledgment of his loyalty, brilliant leadership, kindly sympathy, ready helpfulness and professional ability, it is directed that this resolution of condolence and regret be published in the Journal of the Engineers' Club, together with a sketch of his life."

Possibly the greatest work in which he was ever engaged was his connection with the American Society for Testing Materials. In 1898 he joined the American Section of the International Association for Testing Materials and helped to organize the American Section of that Association. In 1902, when it became evident that a real leader would have to be found to vitalize the Society, the American Section turned to him. A concise statement of this part of his work is given in the following minute on his death which was passed at the October meeting of the Executive Committee of the Society, in 1918:

"In the death of Edgar Marburg, which occurred on June 27th, 1918, the American Society for Testing Materials has suffered the irreparable loss of one of its most eminent and distinguished members; its executive officer since its incorporation; a leader in engineering thought and education and in the field of testing materials.

"He was one of a small group which, in 1898, organized the American Section of the International Association for Testing Materials. In 1902 he was appointed acting secretary of the Section. He at once prepared for the Executive Committee a clear, comprehensive statement of the purposes of a testing society, as he conceived them, which led to the incorporation of the Society as an independent body. He was elected Secretary and Treasurer of the new society, and to him was entrusted the executive direction of its affairs. From then till his death, a period of sixteen years, he worked assiduously for the success and advancement of the Society. He devoted much time and thought to the work of its technical committees and the standardization of specifications and methods of tests of the materials of engineering, and he shaped the policy under which these essential activities of the Society are conducted. The marked success which has attended the work and growth of the Society, and the interest and pleasures of its annual meetings, have been due in a large part to his tireless and painstaking efforts. To his labors he brought great executive and

organizing ability, excellent judgment, a clear grasp of the many and varied problems which confronted him, a sympathetic understanding of humanity, tremendous enthusiasm and zeal, and thoroughness in everything he undertook. His high ideals were reflected in every word and act. He was ever zealous of the good name of the Society and sought throughout his leadership to extend its usefulness in every proper field.

"To the officers and members of the Executive Committee, who were privileged to work intimately with him, his death brings a deep sense of personal loss and grief. His high integrity, his rugged honesty, his open-mindedness, and his evident sincerity of purpose, endeared him to his associates, and commanded their admiration, respect and devotion.

"The character and personality of Edgar Marburg have indelibly impressed themselves upon the American Society for Testing Materials —an inspiration to the Society for all time."

Past-President A. A. Stevenson of the American Society for Testing Materials has kindly prepared the following statement which shows many of the characteristics of the man:

"No doubt the members at large of the American Society for Testing Materials appreciate, in a certain measure, how much Dr. Marburg's connection with the Society had to do with its success. Those of us who as officers of the Society and members of the Executive Committee during Dr. Marburg's tenure of office, had the privilege of working with him, can alone have a full realization of the extent to which his character as a man, with his ideas and ideals, independent of his work, had to do with the growth of the Society in influence and in numbers.

"Any one working with the Doctor could not but have the greatest admiration for him. While at times one might have differed with him, there was never a question as to his motives, or a thought that he was prompted by any other motive than what, in his mind, was best for the Society. Dr. Marburg had at all times the interest of the Society at heart, and no one could have been more jealous of its good name. He would make any sacrifice and go to any length in working to advance its interest. His very enthusiasm and devotion led to overwork, and I have no doubt that this, in connection with his work at the University, was largely one of the causes that led to his untimely death in the prime of life. With it all, one could not but be impressed by the great modesty of the man. He was most bitterly opposed to anything that might seem like self aggrandizement. It was the Society he thought of, and not himself. His desire was to see results; his greatest satisfaction in work accomplished.

"As an officer and member of the Executive Committee I worked with Dr. Marburg seven years; saw a great deal of him, and had many conferences concerning the work and the future of the Society. The official relationship developed into a warm personal friendship that is, and always will be, one of my most cherished memories. His 'Old man, how are you?' over the telephone or when met, is sadly missed.

"To me the most outstanding trait in Dr. Marburg's character was his sterling honesty. He was honest in his ideals, in his work, and in his life. What more fitting tribute could be paid to a man?"

At the Annual Meeting of the American Society for Testing Materials, held in Atlantic City, N. J., in June, 1919, a special Session was held in his honor and addresses were made as follows:

Introductory Remarks.....President G. H. Clamer
Contributions to Engineering.....Mr. John M. Goodell
His Early Activities in the Society.....Mr. Robert W. Lesley
His More Recent Service in the Society....Prof. A. N. Talbot
A Personal Tribute.....Captain Robert W. Hunt

The addresses in full can be found in the *Proceedings* of the American Society for Testing Materials for 1919.

In 1919 the American Society for Testing Materials established an Edgar Marburg Memorial Scholarship in the University of Pennsylvania, to be awarded by the University to a student in the Department of Civil Engineering. The fund for this scholarship ($5 000) was raised by subscription from the members of the Society.

With reference to the above *Engineering News-Record* commented editorially as follows:

"No more appropriate form of memorial to the memory of Edgar Marburg than the proposed permanent scholarship in his own institution, the University of Pennsylvania, to which he gave practically the whole of his working life, could be conceived. The plan by which the American Society for Testing Materials is collecting the fund for a memorial scholarship, is worthy of the highest commendation. This form of recognition would appeal to Dr. Marburg himself, because his whole heart went out in the true teaching instinct to develop young engineers into men worthy of the great profession to which he gave his life. It is to be hoped that the future students who will benefit by this scholarship may fully appreciate the honor and repay it a hundred fold by their later contributions to engineering progress. It is unfortunate that only members of the A. S. T. M. have been asked to subscribe. There is no doubt whatever that thousands of other engineers the country over would be glad to add their tribute to a man who had been their inspiration and guide either in the days of their early training or in their engineering experience."

He acted as Consulting Engineer at various times, notably in the preparation of the design for the Rock Creek Bridge on the line of Massachusetts Avenue, Washington, D. C., under commission for the Corps of Engineers, U. S. A.

In 1904 he was elected Lecturer on Structural Engineering at the Franklin Institute, and he was Past-Chairman of its Committee on Science and the Arts. He was also Secretary of the American Society

for the Promotion of Engineering Education, and Past-President of the honorary society, Sigma Xi.

In addition to a number of papers for the American Society for Testing Materials, his best known contribution to engineering literature is his work on "Framed Structures and Girders—Theory and Practice. Volume 1". This was the first of an unfinished series of three volumes covering the field of structural steel design and erection.

In 1896 he presented a paper before the Engineers' Club of Philadelphia, on "Cantilever Bridges". This notable paper was used in his classes from the time of its presentation.

He also contributed papers to the American Society for the Promotion of Engineering Education. In 1914 he was honored by Franklin and Marshall College with the degree of Doctor of Laws and Letters.

He was married to Miss Fannie Dulany Moncure of Shreveport, La., at Shreveport, on August 14th, 1893. Mrs. Marburg and their four children, Edgar, Mrs. Samuel T. Ziegler, Clara, and Anita survive him.

He was elected a Member of the American Society of Civil Engineers on October 6th, 1897.

WILLIAM AUGUSTUS MONCURE, M. Am. Soc. C. E.*

DIED OCTOBER 3D, 1918.

William Augustus Moncure, son of the late Thomas Jefferson Moncure and Margaret Elizabeth Moncure, was born near Falmouth, Va., on February 26th, 1870.

After completing his studies in the Suffolk Military Academy, he entered the Virginia Military Institute, from which he was graduated in 1889. After his graduation, he immediately began to engage actively in his chosen profession as a Civil Engineer.

During the summers of 1886 to 1889, he was employed as Rodman and Instrumentman by the Seaboard Air Line Railway. From October, 1889, to September, 1891, he was with the Richmond and Danville Railroad, as follows: From October to December, 1889, as Draftsman in the Chief Engineer's office; from December, 1889, to May, 1890, as Leveler and Transitman; and from May, 1890, to September, 1891, as Resident Engineer in charge of construction.

From February to October, 1892, Mr. Moncure was Assistant to the Engineer in charge of construction on the Ohio Extension of the Norfolk and Western Railroad; and from November, 1892, to September, 1893, he was Levelman and Transitman in charge of change in line and construction work on the Philadelphia Division of the Pennsylvania Railroad.

From December, 1893, to March, 1894, he was engaged in the Department of Sewers, Washington, D. C., and, during the latter month, with the Pennsylvania Railroad. Then, until April, 1895, he was engaged on resurveys of portions of the Monongahela, Maryland, and New York Divisions, and from April, 1895, to April, 1897, he was Principal Assistant to the Engineer in charge of important changes on the Philadelphia and New York Divisions.

In May, 1897, Mr. Moncure was appointed Assistant Engineer in the Engineering Department of the Pennsylvania Railroad, and in January, 1900, was transferred to the Real Estate Department, where, until January, 1902, he was in charge of the engineering and drafting force. Then, until June, 1906, he was Principal Right of Way Agent, and in January, 1907, was appointed Engineer of Right of Way. In January, 1913, he was made Assistant Real Estate Agent, and in July, 1918, Real Estate Agent.

In getting off a train at Fredericksburg, Va., Mr. Moncure was injured seriously, and died in the Mary Washington Hospital at Fredericksburg, on October 3d, 1918.

* Memoir prepared by H. E. Tripler, Esq.

On November 6th, 1895, Mr. Moncure was married to Miss Caroline Ashe Pemberton, of Albemarle, N. C., who, with three daughters and four sons, survives him.

Mr. Moncure was elected a Junior of the American Society of Civil Engineers on June 21st, 1894, an Associate Member on October 7th, 1896, and a Member on June 5th, 1906.

AUGUSTUS MORDECAI, M. Am. Soc. C. E.*

DIED JULY 28TH, 1918.

Augustus Mordecai, son of the late Maj. Alfred Mordecai and Sara Hays Mordecai, was born in Philadelphia, Pa., on September 8th, 1847.

He attended the Polytechnic College of Pennsylvania, from which he was graduated in June, 1866, and then, for about a year, served as a Rodman on the construction of the Dutchess and Columbia Railroad, now a part of the Central New England System.

During the next four years Mr. Mordecai was in charge of construction divisions, successively, on the Connecticut Western Railroad (now also a part of the Central New England System), on the St. Louis, Council Bluffs, and Omaha Railroad (now a part of the Missouri Pacific System), and on the Pittsburgh, Virginia, and Charleston Railroad (now a part of the Pennsylvania System), remaining on each work until its completion.

In 1872, Mr. Mordecai went to Cleveland, Ohio, as Division Engineer in charge of maintenance on the Atlantic and Great Western Railroad, which was afterward merged into the present Erie Railroad System. For twenty years he remained in Cleveland, associated with the Erie road and its successors, filling the positions, successively, of Division Engineer, Resident Engineer, and General Roadmaster. In 1892, he was appointed Chief Engineer of the Erie System, with headquarters in New York City, and served in that capacity until 1896. For ten years thereafter he resided in Cleveland as Assistant Chief Engineer in charge of construction and maintenance on all the lines of the Erie System from Salamanca to Chicago, and was then appointed Chief Engineer of the Lorain and Ashland Railroad, in charge of the location and construction of that line. He was afterward associated with J. F. Stevens, M. Am. Soc. C. E., as Office Engineer in the valuation of the New York, New Haven, and Hartford Railroad, until the completion of that work.

From 1909, Mr. Mordecai was active in Cleveland as a Consulting Engineer, notably in connection with the Belt Line around Cleveland, and with valuations of the properties of the New York Central, the New York, New Haven, and Hartford, the Lehigh Valley, and the Canadian Pacific Railroad Companies, and also the Detroit United Street Railway Company. Up to the time of his fatal illness, he was engaged in similar work for the Erie Railroad Company. In 1912, he was appointed, by the Mayor of Cleveland, a member of that city's River and Harbor Commission.

In Cleveland, on October 14th, 1897, Mr. Mordecai was married to Miss Margaret Bowman, who survives him.

* Memoir prepared by John C. Trautwine, Jr., Assoc. Am. Soc. C. E.

Mr. Mordecai's kindly and unassuming nature, his sterling integrity, and his fine sense of humor endeared him to all who had the good fortune to know him.

Mr. Mordecai became a Member of the American Railway Engineering Association in 1909, and was one of the original members of the Cleveland Engineering Society. He was elected a Member of the American Society of Civil Engineers on February 1st, 1893, and served as a Director for the period 1895-97.

CHARLES JOHN AUGUSTUS MORRIS, M. Am. Soc. C. E.*

DIED OCTOBER 28TH, 1918.

Charles John Augustus Morris, the son of Charles A. F. and Mary Ellen Morris (*nee* Lane), was born in Brooklyn, N. Y., on July 26th, 1850.

His early education was obtained in public and private schools, his professional education and training being acquired later under the tutorage of his father, a graduate of Dublin University and a prominent and experienced civil engineer and contractor, who, for many years, was one of the leading pioneer civil engineers in railway construction work in the earlier days of the Northwestern States.

So far as can be learned, the first important engineering work performed by Charles John Augustus Morris consisted of the survey and location, in 1871, of an extension of the St. Paul and Pacific Railroad from a point now occupied by Barnesville, Minn., to St. Vincent, on the northern boundary of the State. In 1875 and 1876, Mr. Morris was similarly engaged on surveys for the St. Paul and Pacific Railroad in the western part of Minnesota.

In 1878, he was engaged on Government work at Rock Island, Ill., and, during 1879, was employed in the United States Government Engineer's office in St. Paul, Minn., under Maj. Allen, of the U. S. Corps of Engineers. In 1880, Mr. Morris had charge of the construction of a water-power canal for the Pillsbury "A" Mill, at the Falls of St. Anthony, in Minneapolis, Minn.

In 1881, he was employed by the St. Paul, Minneapolis and Manitoba Railway Company on bridge, trackage, and other construction work, and in 1882, 1883, and part of 1884, he made the surveys and located the present Stone Arch Bridge across the Mississippi River, for the Minneapolis Union Railway Company. During the construction of this noteworthy bridge, he was the Supervising Engineer in charge, the Chief Engineer being the late Col. C. C. Smith, M. Am. Soc. C. E., of the Great Northern Railway Company. During this period Mr. Morris was also in charge of the re-arrangement of trackage for the new Union Station in Minneapolis and the construction of the buildings forming that station; he remained in the employ of the Great Northern Railway Company until 1887.

From 1888 to 1890, Mr. Morris was a member of the contracting firm of McMullen and Morris, engaged in heavy masonry work, particularly in constructing large retaining walls in St. Paul and Minneapolis in connection with the lowering of track grades. During this time, he also had charge of the work of erecting the foundation piers for the High Bridge in St. Paul.

* Memoir prepared by William de la Barre, M. Am. Soc. C. E.

On March 22d, 1888, he was appointed Chief Engineer of the St. Paul and Duluth Railway Company, and continued in that position until June 15th, 1890, at which time the property was taken over by the Northern Pacific Railway Company. Mr. Morris then entered the construction field as a member of the firm of Frankman Brothers and Morris.

During 1891 and 1892, he was Chief Engineer of the Minneapolis Western Railway Company, having charge, among other matters, of the design, construction, and erection of the steel railway bridge over the Mississippi River immediately below the Falls of St. Anthony. During this period he also acted as Consulting Engineer for the Northwestern Fuel Company in connection with the design and construction of its coal dock substructure at Superior, Wis. The firm of Frankman Brothers and Morris also constructed the timber cribbing and timber coal bins of Section No. 1 of the Northwestern Fuel Company's Superior Dock No. 1 on Connor's Point, as well as the timber cribbing for the Company's Coal Dock No. 2 on St. Louis Bay, near Duluth.

From September, 1895, to January, 1898, Mr. Morris was engaged in superintending the construction of the St. Anthony Falls Water-power Company's lower dam and power house, including the hydro-electric development of 10 000 h. p., below the Falls of St. Anthony.

From 1900 to 1904, he was actively employed in various engineering and construction works at the head of Lake Superior, particularly at Duluth, Two Harbors, and Superior, as Chief Engineer of companies handling coal and iron ore, continuing in that capacity until the Northwestern Fuel Company's property was acquired by the Pittsburgh Coal Company. It was under his direction and superintendence, that the first hydraulic dredge on the Great Lakes was constructed and put in operation. During this period he designed and supervised the construction of Dock No. 5, at Duluth, for the Pittsburgh Coal Company, with a storage space of 400 by 1 000 ft. with forty stationary hoists. Later, this storage space was lengthened to 1 360 ft., and four movable hoists were added to the equipment. In 1906, the firm of Frankman Brothers and Morris constructed the timber cribbing and anthracite storage building, of 2 000 000 tons storage capacity, on Section No. 2 of the Northwestern Fuel Company's Dock No. 1 at Superior, Wis.

From July, 1907, to June, 1908, Frankman Brothers and Morris was engaged in the erection, for the Northern Pacific Railway Company, of its Valley City, N. Dak., viaduct, which is one of the largest and heaviest viaducts in the Northwest, being about 3 000 ft. long and 150 ft. high, with double-track towers and substructures, the erection of which covered the placing of more than 7 000 tons of steel.

In 1907, Mr. Morris was also employed as Consulting Engineer and had charge of the construction of Dock No. 1 of the Berwind Fuel

Company at Superior, Wis., and, at about this period, he was also engaged in the construction of additional dock facilities at both Superior and Duluth.

In 1909 he became the senior partner of the contracting firm of Morris and Shepard (changed in 1912 to Morris, Shepard and Dougherty), which firm was subsequently engaged in various railway construction work for the Chicago, Milwaukee and St. Paul Railway Company, the Chicago, Burlington and Quincy Railway Company, and the Great Northern and Northern Pacific Railway Companies and, in addition, in dock construction work at the head of the Lakes.

At the time of his death, the firm of Morris and Dougherty (Mr. Shepard having retired) and the George J. Grant Construction Company had the contract with the Union Depot Company of St. Paul, Minn., for the design and construction of the new Union Station in that city and the building of the various adjacent yard systems connected therewith.

Mr. Morris was married, on December 31st, 1878, at Cleveland, Ohio, to Sarah R. Saunders, who survives him; other surviving relatives are two brothers and two sisters.

He was a member of the Civil Engineers Club of St. Paul, Minn., Minnesota Club, St. Paul Athletic Club, University Club, and Town and Country Club, all of the same city.

Mr. Morris was a gentleman with whom it was a genuine pleasure to be acquainted and associated. His ideals were always of the highest character, and, equally as a friend or business associate, he was thoroughly faithful, conscientious, and reliable, and was held in high esteem by employer and employee alike. He was energetic and resourceful to a high degree, and his ability as an engineer, together with his pleasing and tactful personality, contributed largely in insuring the success of his business life.

Mr. Morris was elected a Member of the American Society of Civil Engineers on October 3d, 1883.

HENRY PRENTICE MORRISON, M. Am. Soc. C. E.*

DIED DECEMBER 17TH, 1918.

Henry Prentice Morrison was born in Troy, N. Y., on January 14th, 1857. At an early age he came to New York City with his parents and settled on the lower west side, where he lived for many years. He was educated in the public schools, and was graduated from New York University in 1880, with the degrees of B. Sc. and C. E. For a short time after his graduation he served as Assistant to Mr. George N. Harris, on the Baltimore and Ohio Railroad.

In March, 1881, Mr. Morrison entered the Department of Public Works of the City of New York, where he remained until 1893. During these 12 years he served as Assistant to the late Stevenson Towle, M. Am. Soc. C. E., in the Bureau of Sewers; in the Bureau of the Water Purveyor; and with Horace Loomis, M. Am. Soc. C. E., as Principal Assistant in charge of establishing lines and grades, and the construction of pavements.

In 1889, under a special repaving law, he had charge of all repaving work in New York City below 14th Street, including stone block, asphalt, brick, Telford, and wooden pavements.

In the early part of 1893 Mr. Morrison was appointed by the Supervisors as Engineer of County Roads for the County of Richmond, and, as such, under what was known as the County Road Law, had charge of the preparation of surveys, plans, and specifications for the construction of about 100 miles of modern macadam and block pavements. Of these, 55 miles were completed under his supervision, and, in addition, he designed and superintended the construction of five masonry, brick, and steel highway bridges, two steel swing-bridges, and a wooden trestle roadway, 1 800 ft. long.

He also had charge of the building of 30 miles of trolley railroads, heavy retaining walls, sewers, dock improvements, and a water supply system for the county buildings. In addition, as County Engineer, he had charge of the maintenance of all county roads.

Mr. Morrison served in this position with distinction until consolidation with the City of New York, on January 1st, 1898, when he automatically became connected with the new City Government. He was appointed, by Mayor Van Wyck, Deputy Commissioner of the Departments of Highways, Sewers, and Water Supply, and Chief Engineer of the two first-named Departments. This combining of five positions under one official was done for reasons of economy, as it was deemed extravagant at that time to have three fully developed departments in the Borough of Richmond. For four years, or until the begin-

* Memoir prepared by Theodor S. Oxholm, M. Am. Soc. C. E.

ning of 1902, he had charge of all improvements and maintenance work in the Borough of Richmond. On January 1st, 1902, the revised Charter of the City went into effect, giving each Borough autonomy under its Borough President, and abolishing the former departments. After reorganizing the old departments into bureaus, and placing the construction work, maintenance, and Bureau of Street Cleaning on a good working basis, which he did at the request of Borough President George Cromwell, he separated from the City service and entered into private practice, with offices in the Park Row Building, New York City.

For the next 13 years Mr. Morrison prosecuted a general engineering practice, and in 1913 and 1914 he was specially engaged by the Governor of New York to investigate the frauds in the building of State roads. He was also appointed City School Commissioner in 1912, and served for two years. In September, 1915, he was appointed Commissioner of Public Works for the Borough of Richmond by President Calvin D. Van Name, in which position he served until his death.

Mr. Morrison's skill and experience as a road engineer will be greatly missed in New York City. His ability as a public speaker and his great interest in all educational matters made it impossible to have a successful meeting, public dinner, or entertainment, in the Borough of Richmond, without his active presence.

His friends remember him as a man of most pleasing personality, a ready wit, most entertaining on all occasions, an astute politician, and one whose advice was much sought. His associates in the Department of Public Works miss his sound and practical judgment and advice on important matters.

On April 30th, 1890, he was married to Miss Belle A. Von Eiff, of Brooklyn, N. Y., who survives him.

Mr. Morrison was elected a member of the American Society of Civil Engineers on April 6th, 1898.

CLARENCE RUFUS NEHER, M. Am. Soc. C. E.*

DIED MAY 13TH, 1918.

Clarence Rufus Neher was born in Ashokan, Ulster County, N. Y., on February 27th, 1860. He was educated in the public schools at Ashokan, and at the Academy at Nassau, N. Y.

About 1881, Mr. Neher joined the Engineering Corps of the Genesee Valley Canal Railroad, at Nunda, N. Y., now the Rochester Division of the Pennsylvania Railroad. In 1884 he accepted the position of Assistant Engineer on the Washington and Ohio Railroad, in Virginia, under Robert Bell, Chief Engineer. Between 1887 and 1889 he was employed as Engineer in the Maintenance of Way Department of the Richmond and Danville Railroad, with headquarters at Greensboro, N. C. In 1889 he became Engineer in the Maintenance of Way Department of the Western New York and Pennsylvania Railroad, now the Rochester Division of the Pennsylvania Railroad, with headquarters at Rochester, N. Y. He held this position about nine years, or until 1898, and then resigned to become Resident Engineer in the New York State Engineer's Department on the Western Division, with headquarters at Rochester, N. Y.

About 1900 Mr. Neher resigned this position and was appointed Engineer for the Donnelly Construction Company, of Buffalo, N. Y., remaining with the Company while the foundations for the Great Eastern and Dakota grain elevators, and other important work near Buffalo, were built. In 1901 he became Engineer and General Manager of the Continental Engineering and Contracting Company, of Buffalo, N. Y., and, in this capacity had charge of building the concrete foundations and floors of the grain elevator of the Board of Harbor Commissioners, at Montreal, Que., Canada, and also a large grain elevator at Fort William, Ont., Canada. He also had charge of building all the concrete structures on the Buffalo and Susquehanna Railroad, and the concrete dam across the Cumberland River at Burnside, Ky.

About 1909 Mr. Neher was made Engineer for the Atlantic, Gulf and Pacific Company and had charge of the engineering work on 12 miles of Barge Canal contracts between Smith's Basin and Whitehall, N. Y.

About 1912 Mr. Neher entered the service of the Buffalo Dredging Company, of Buffalo, N. Y., as Engineer and General Manager. While with this company he had charge of completing the large Barge Canal Dam at Hinckley, N. Y., and constructing the new double-track line of the International Railway Company, between Buffalo and

* Memoir prepared by Henry A. Van Alstyne, M. Am. Soc. C. E.

Niagara Falls, N. Y. He was in the employ of this company at the time of his death.

Mr. Neher was a very capable and energetic man, of high character and pleasing personality. He was married in 1882 to Nellie Louise Dodge, of Mount Morris, N. Y., who died in 1913, leaving two sons, Carl Clarence and Roy Herbert Neher. In February, 1917, he was married to Miss Janet Alison Carmichael, of Albany, N. Y., who survives him.

Mr. Neher was elected a Member of the American Society of Civil Engineers on June 4th, 1902.

WILLIAM NEWBROUGH, M. Am. Soc. C. E.*

DIED NOVEMBER 2D, 1919.

William Newbrough was born at Philadelphia, Pa., on December 15th, 1860. After receiving his preparatory training at Dr. Sach's School, he entered Columbia University, New York City, in 1876, and was graduated from the School of Mines in 1884 with the degree of E. M. He received his A. M. degree in 1885.

From 1884 to 1886, he was Instructor in Civil Engineering at Lafayette College, and from 1886 to 1888 acted as Instrumentman and Bridge Engineer with the Atchison, Topeka and Santa Fé Railroad.

During 1888-89, Mr. Newbrough served as Professor of Engineering in the State College of Kentucky, and for the two years following he was in private practice and also held a position as Computer in the United States Surveyor-General's Office, at Salt Lake City, Utah. He continued private practice in the latter city until 1900, including among his more important work, Contract 188 for the survey of the Public Lands of the United States in Utah, the duties of Chief Engineer of the Lucerne Land and Water Company, and the design, location, and construction of 14 miles of a canal crossing three divides and costing $23 000.

In 1892 Mr. Newbrough designed and located the Black's Fork and Twin Butte Canals at Fort Bridges, Wyo., which were enlarged, later, partly by himself. From 1894 to 1896 he was engaged on surveys, statistics, tracing coal veins and outcrops, general exploratory work, assessments, etc., for Mr. P. J. Quealy of Kemmerer, Wyo., in connection with the development of the Kemmerer coal deposits, and from 1896 to 1900, he was employed as Engineer for Quealy and Kemmerer and the Kemmerer Coal Company, having full charge of all engineering work. He also laid out the Town of Kemmerer and designed its waterworks.

In 1900, Mr. Newbrough went to Detroit, Mich., as Acting Assistant Superintendent of the Penberthy Injector Company. In 1902, he returned to Evanston, Wyo., and immediately was engaged as Consulting Engineer by the Kemmerer Coal Company. In 1903 he was appointed Engineer of the Diamond Coal and Coke Company, Diamondville, Wyo., and from 1902 to 1904 acted as Engineer for Beckwith, Quinn, and Company, Evanston, Wyo.

In 1905, Mr. Newbrough engaged in private practice as a Civil and Mining Engineer with an office at Evanston, Wyo., until 1914, when he returned to Detroit, Mich., as General Superintendent of the Penberthy

* Memoir prepared from information on file at the Headquarters of the Society.

Injector Company. He remained with this company until 1916, when he opened an office as a Consulting Engineer at Kemmerer, Wyo., which he continued until his death on November 2d, 1919.

Mr. Newbrough was married to Gertrude Sturtevant, of Brooklyn, N. Y., in January, 1897. She died in 1917. He is survived by a sister, Elizabeth Newbrough.

Mr. Newbrough was elected a Member of the American Society of Civil Engineers on April 6th, 1904.

LEWIS ABEL NICHOLS, M. Am. Soc. C. E.*

DIED MARCH 5TH, 1919.

Lewis Abel Nichols was born in Florence, Italy, on August 26th, 1851, of American and English parents. After his mother's death in 1856, his father returned to the United States with his family, and settled in Danvers, Mass. He died in 1858, and Mr. Nichols was left an orphan at the age of seven.

After attending the public schools and High School at Danvers, he entered the Massachusetts Agricultural College at Amherst, Mass., in 1867, and was graduated in 1871, in the pioneer class of that institution.

Having chosen Civil Engineering as a profession, Mr. Nichols began his life work in the fall of 1871, by laying out town lots in an addition to the City of Fall River, Mass. During the latter part of the same year, he was employed as a Leveler on the location of the Massachusetts Central Railroad. In 1872 he was placed in charge of the party and finished the location and construction of a Division of the railroad in the fall of 1873.

In 1874 and 1875, Mr. Nichols was engaged in private practice in Eastern Massachusetts. He was elected City Engineer of Chelsea, Mass., in 1875 and retained this office until 1877, when he resigned to take charge of the Marblehead Water-Works. In 1878 he resumed his private practice, maintaining an office in Boston for two years.

During 1880 and 1881, Mr. Nichols was a Transitman on reconnaissance, preliminary, and location surveys in New Mexico and Arizona, for the Atchison, Topeka and Santa Fé Railroad. In the latter year, he was appointed Division Engineer on the California Southern Railroad, and was in charge of some particularly heavy and difficult work in the Temecula Canyon, California. During 1883 and 1884, he was employed as Division Engineer on the Tampico Division of the Mexican Central Railroad, in charge of the location and construction of more than 100 miles of heavy mountain road.

Mr. Nichols was Engineer of Buildings on the Chicago, Burlington, and Northern Railroad in 1886, and, in the spring of 1887, became Locating Engineer for that road on projected branches. He was Assistant Chief Engineer on the Illinois Valley and Northern Railroad in 1887 and 1888, and, in the latter year, Locating Engineer on the Oregon Railway and Navigation Company's extension through Idaho. In 1889 he was Office Engineer on the Toledo, St. Louis and Kansas City Railroad, and, in 1890, built some exceptionally heavy and difficult work on the Cumberland Valley Extension. During 1891 he served as Locating Engineer on the Toledo and Chicago Bee Line, but it was not built. Mr. Nichols then became Chief Engineer of the

*Memoir prepared from information on file at the Headquarters of the Society.

La Salle and Bureau County Railroad, a belt line to connect the Illinois Central, Chicago, Burlington, and Quincy, and the Chicago and Northwestern Railroads in the vicinity of La Salle, Ill.

The foregoing gives some indication of the extensive and responsible railroad work done by Mr. Nichols. In 1908, he gave up the active practice of his profession, except as a Consulting Engineer, and devoted most of his time to the interests of the Chicago Steel Tape Company, a corporation which he organized in 1903, and of which he was President at the time of his death.

Mr. Nichols was married in 1879, to Miss Carrie W. Putnam of Danvers, Mass. They had no children.

He was a member of the Woodlawn Park Lodge, A. F. and A. M., of Chicago. He was also a member of the Western Society of Engineers and several other technical societies.

Mr. Nichols was elected a Member of the American Society of Civil Engineers on October 5th, 1892.

ALEXANDER JOSEPH NORRIS, M. Am. Soc. C. E.*

DIED MAY 30TH, 1918.

Alexander Joseph Norris was born on November 4th, 1864, at Vera Cruz, Mexico, where his father, Henry De Butts Norris, one of the early associates of William R. Grace in railway construction in South America, was engaged in building a railroad. The boy studied under private tutors, but was sent to the United States to complete his education, and was graduated from Rensselaer Polytechnic Institute in June, 1886, with the degree of Civil Engineer.

Mr. Norris began his engineering career as Draftsman for the Phœnix Bridge Company, at Phœnixville, Pa., and was engaged in that capacity and also on special bridge inspection for M. S. Carter and Company, of St. Louis, Mo., and for the Missouri Pacific Railroad Company, from November, 1886, to September, 1887.

From September, 1887, to March, 1889, he was employed by the City of New York as Inspector on street paving, and, after April, 1888, was in charge of all paving for the city north of 59th Street and east of Fifth Avenue. He then went to the Connecticut River Granite Company, of Lyme, Conn., as Superintendent, which position he held until June, 1890, when he was appointed Assistant Engineer on his father's staff with the Peruvian Corporation, Limited, of London, and made reconnaissances and preliminary surveys and estimates for railways in Peru and Bolivia, as well as examinations and reports for the reconstruction and equipment of practically all the railroads in Peru.

In 1891, Mr. Norris was appointed first as Engineer on the location of a 50-mile extension of the Southern Railway (Ferrocarril del Sud) and afterward as Chief Engineer of Construction, designing all bridges, culverts, stations, etc.

From July, 1893, to November, 1894, he was employed as Assistant Engineer with the City of New Orleans, on drainage work for that city. While in this position illness in the family compelled Mr. Norris to resign and take charge of his father's business affairs, in which he continued until June, 1896. He then engaged in private practice as a member of the firm of Pratt and Norris, of Essex, Conn., quarry operators and general contractors for the construction of breakwaters, buildings, and all classes of stone work.

In November, 1897, Mr. Norris was appointed Assistant Engineer on the Nicaragua Canal Commission with which he remained until March, 1901, serving for 10 months in Nicaragua as Transitman and Chief of Party, and the remainder of the time in Washington, D. C., on estimates, drafting plans, etc.

* Memoir prepared from information on file at the Headquarters of the Society.

In March, 1901, Mr. Norris again engaged in the private practice of engineering as senior member of the firm of A. J. Norris and Company, Contractors, which firm built part of the electric railway between Amsterdam and Schenectady, N. Y. In November, 1901, he organized the firm of Norris and Penguet, and was engaged on contract work for the Chesapeake and Ohio Railroad on the Big Sandy River in Kentucky, as well as for the Deepwater Railroad in West Virginia.

In March, 1906, Mr. Norris went to Peru as Chief Engineer of the Ferrocarril Central del Peru, and remained in that country until his death on May 30th, 1918. During this time he served as Engineer in charge of a 60-mile extension of the Central Railway of Peru; Engineer in charge of the Chilete Extension of the Pacasmayso and Guadalupe Railway; and as Chief Engineer in charge of all construction and maintenance for the Peruvian Corporation, Limited, of London, which position he held at the time of his death.

The greatest railway construction project with which Mr. Norris was connected, and in which his engineering skill was shown, was the successful construction of the railroads, reaching an altitude of practically 16 000 ft., over the Peruvian Andes, and their subsequent maintenance and improvement, which work brought him international fame.

Mr. Norris was married in November, 1893, to Frederika H., the only child of Capt. Henry C. Henshaw, U. S. A. (*Retired*), who, with two sons and a daughter, survives him.

In recognition of his work in Peru, Mr. Norris was the recipient of many honors, among which were medals awarded by various scientific societies and by the Government of Peru. He was frequently sent as a representative, both by the Peruvian Government and the Peruvian Corporation, Limited, on important missions to Europe and the United States, and was widely known in the Latin-American countries, where the news of his death was received with sincere regret and sorrow by his many friends.

Mr. Norris was elected a Member of the American Society of Civil Engineers on October 3d, 1911.

JOHN PATRICK O'DONNELL, M. Am. Soc. C. E.*

DIED DECEMBER 2D, 1919.

John Patrick O'Donnell was born in Dublin, Ireland, on July 1st, 1859.

He was articled with Messrs. Stevens and Sons, Railway Signaling Engineers, of London and Glasgow, in 1875, and served with that firm until 1882, when he was appointed Assistant Signal Superintendent on the Lancashire and Yorkshire Railway.

From 1885 to 1889 Mr. O'Donnell was in the service of the London and South Western Railway, under Mr. Jacomb, Chief Engineer, and during this period he designed and carried out extensive alterations to the signaling system at Waterloo Station in London, and other works, for that company. Subsequently, he joined Mr. Dutton in establishing the firm of Dutton and Company, Railway Signaling Engineers, of London and Worcester, leaving the firm in 1894 to join the late Mr. A. G. Evans, in founding the firm of Evans, O'Donnell and Company, Railway Signal Works, Chippenham and London, which carried out many extensive signaling works in England and abroad. Evans, O'Donnell and Company subsequently amalgamated with Saxby and Farmer, Limited, and Mr. O'Donnell held the position of Joint Managing Director for a number of years.

In 1901 he formed the British Pneumatic Railway Signal Company, of which he was Chairman and Managing Director until his death. Mr. O'Donnell started the first works for the manufacture of pneumatic tools on a considerable scale in Great Britain, and was one of the pioneers of power signaling there. He installed the first automatic signals on main passenger lines, *viz.*, on the South Western Railway between Grateley and Andover, and subsequently between Woking and Basingstoke. The first power signals installed on passenger lines in Great Britain were put in at Grateley on the South Western Railway by Mr. O'Donnell who was, also, one of the earliest advocates of concentration sidings and hump shunting, and established the big installation at Wath on the Great Central Railway.

Extensive contracts were carried out under his direction on the Great Central Railway, the London and Southwestern Railway, and the Central Argentine Railway, etc. At Victoria Station (South Eastern and Chatham Railway) the latest form of signaling—three-position, all electric interlocking—was finished at the time of his death.

Mr. O'Donnell was the inventor of a large number of appliances for railway signaling and kindred subjects, and was always well to the

* Memoir prepared by J. Groom, Esq.

fore in civil and mechanical engineering developments in connection with railways.

He was a Member of the following: Institution of Civil Engineers (Great Britain), Institution of Mechanical Engineers, Canadian Society of Civil Engineers, Railway Signal Association, and the Institution of Railway Signal Engineers. He was a Fellow of the Chartered Institute of Patent Agents.

At the time of his death Mr. O'Donnell held, among others, the following positions: Managing Director of the Superheater Corporation, Limited; Managing Director of the British Power Railway Signal Company, Limited; and Managing Director of the Economical Boiler Washing Company, Limited.

Mr. O'Donnell was elected a Member of the American Society of Civil Engineers on July 5th, 1893.

JOHN CHRISTIAN OSTRUP, M. Am. Soc. C. E.*

DIED FEBRUARY 27TH, 1919.

John Christian Ostrup was born on an estate near Frederickshaven, Denmark, on August 31st, 1867. He received his early education at a private school in Frederickshaven and his principal technical training, including thorough military instruction, at the Royal Danish Military Academy, from which institution he was graduated in 1888. He remained in the Danish Army as Lieutenant for two or three years.

In 1891 Mr. Ostrup came to the United States and immediately supplemented his technical education by night work at an engineering school in Chicago, Ill., mainly for the purpose of learning English technical terms. He was graduated from that school in 1892. After obtaining his degree there, he engaged in various enterprises in different parts of the United States, beginning with the design of the Machinery Building for the Chicago World's Fair, and afterward including much work with the writer, first, on the Northwestern Elevated, Union Loop Elevated, and Lake Street Elevated Railroads, of Chicago, and, later, on the Elevated Railroad of Boston, Mass. On these vast enterprises he did effective and important work and held responsible positions. At first, his chief occupation was in the field, but, later, he did considerable structural steel designing, especially for the Boston Elevated, including the entire design of its great terminal building. On the completion of the latter, Mr. Ostrup spent a few years in private practice, mainly in the designing of power houses, industrial plants, etc., and the sheds to contain them; he then entered the employ of the American Bridge Company, where he remained for several years. While with that organization, he detailed, among other structures, the Manhattan Bridge.

From 1907 to 1911 he was Professor of Structural Engineering at Stevens Institute of Technology, Hoboken, N. J., giving there a most successful and popular course, notwithstanding the fact that he was handling a civil engineering department in a mechanical engineering school. It was at that time that he wrote and issued his excellent book, known to the Profession as "Ostrup's Specifications," which deals with methods of modern engineering. It has been widely used in military academies throughout the country, including West Point.

After four years' service at teaching, Mr. Ostrup resigned his position as Professor at Stevens Institute to take that of Chief Engineer to the Texas Company, with headquarters in New York City; and he handled with phenomenal success all the important engineering problems of the vast and diversified business of that company until it appeared probable that the United States would enter the World War, when he at once tendered his services to the Government of the land of

* Memoir prepared by J. A. L. Waddell, M. Am. Soc. C. E.

his adoption. Having been thoroughly trained in military engineering in Denmark, his offer was gladly accepted, and he was given the rank of Major early in January, 1917. He sailed for France that year with the first detachment of the American Expeditionary Force, following General Pershing, to whose staff he had been assigned as an expert on engineering. During the war Maj. Ostrup saw continuous service at various points along the entire western front, his special duties being the supervision of the building of trench fortifications and bridges, where his knowledge of concrete construction proved of great value. In fact, he showed such unusual ability that, after a year at the front, he was returned to the United States to instruct new officers in the principles and practice of modern warfare. He continued his work as Instructor until after the declaration of the Armistice, when he tendered his resignation and asked for its speedy acceptance. He was urged to remain permanently in the United States Army, but refused, owing to ill health caused by over-work and an attack of influenza contracted while in France and from which he had never fully recovered. As soon as he was released from the Army, he returned to his old position with the Texas Company and resumed his former work.

On February 19th, 1919, Maj. Ostrup took lunch with the writer, and spent the better part of two hours in discussing his experiences abroad. It appears that, although often under fire, he was never wounded, although once his clothing was torn by a piece of shrapnel. His description of his work "over there" and of life in the trenches was intensely interesting, especially as he and the writer had been close friends for more than a quarter of a century. Among other things he mentioned the fact that, owing to the great amount of business done by the Texas Company during the war, his stock therein had brought such big returns as to render him independent for the rest of his life, and he was seriously considering retiring soon from active practice—but, alas! it was not to be; for that very evening he was stricken with influenza, which soon turned into pneumonia, to which he succumbed a week later.

Maj. Ostrup was a man of strong personality, an accomplished linguist, speaking several languages fluently and well, and having a reading knowledge of others, a deep student of applied science as well as of economics and the humanities, a good technical writer, an engineer of high attainments, a military officer of courage and of unusual ability, an accomplished musician, a true and loyal friend, and a thorough gentleman. In his premature death the Engineering Profession has sustained a real loss, and many members thereof have suffered a bereavement which will long be remembered.

Maj. Ostrup was elected an Associate Member of the American Society of Civil Engineers on March 4th, 1896, and a Member on March 1st, 1899.

HENRY KINDER OWENS, M. Am. Soc. C. E.*

DIED MAY 15TH, 1919.

Henry Kinder Owens, the son of William D. and Mary J. (Milham) Owens, was born in Wilmington, Del., on October 9th, 1858. Early in his life, the family removed to Missouri where the boy acquired his basic professional education, obtaining a C. E. degree in 1880.

Following his graduation, Mr. Owens engaged in railroad location and construction work in Missouri, Arkansas, and New Mexico. He went to the State (then Territory) of Washington in 1886 and began to interest himself in irrigation projects, in conjunction with railroad development, in Eastern Washington and Oregon. In 1887, he located in Seattle and was engaged as Construction Engineer on the Seattle, Lake Shore, and Eastern Railway, now a part of the Northern Pacific System.

In 1888, Mr. Owens entered into partnership with the late John G. Scurry, under the firm name of Scurry and Owens, and from 1888 to 1890, inclusive, this firm did the engineering work of the City of Seattle, including the replatting and regrading of the business district following the disastrous fire of June 6th, 1889. The firm also participated in the original plans of the present water supply and sewerage systems of Seattle, in collaboration with the late Benezette Williams, Consulting Engineer, of Chicago, Ill. The firm dissolved in 1892, and Mr. Owens planned and constructed water-works plants for some of the smaller communities in the State of Washington.

From 1893 to 1897, he held a special assignment with the Land Department of the Northern Pacific Railway Company, as Irrigation Engineer, in which capacity he made examinations, preliminary surveys, and reports, with estimates of construction costs, for projects embracing a large part of the irrigable lands in the land grant of that company, in Oregon, Washington, Idaho, and Montana. In 1898, he became Consulting Engineer for the Northern Pacific Irrigation and Land Company, in the execution of a project watering 110 000 acres in Yakima Valley. This project has been in successful operation for nearly 20 years.

Thereafter, he was Chief Engineer of the Hanford Irrigation and Power Company, as well as the Pasco Power and Water Company, and works of magnitude were built under his direction.

From 1908 to his death, Mr. Owens maintained an office in Seattle, as Consulting Engineer, in which period he successfully carried out many undertakings in hydraulic and railroad work, as well as in mining, sewerage, irrigation, and power plants, including among

* Memoir prepared by A. V. Bouillon, M. Am. Soc. C. E.

others, notably, the 20 000-kw., hydro-electric plant known as the Puntledge River Plant, built in 1911-13 for the Canadian Collieries, Limited, one of the McKenzie and Mann corporations in British Columbia. He also developed preliminary plans and estimates for numerous hydro-electric projects in Western Washington, and was interested in the development of the steel and nitrate industries in conjunction with hydro-electric power for this district. During part of this period (1911-17), he was associated with A. V. Bouillon, M. Am. Soc. C. E., also a Consulting Engineer of Seattle.

Mr. Owens possessed a genial character which was a source of pleasure to his associates. Always unassuming in manner, he never claimed the professional distinction to which his ability and accomplishments entitled him.

He was married on May 5th, 1887, at North Yakima, Wash., to Miss Alice M. Cock, who, with two sons, Henry Victor Owens, of Seattle, Wash., and Lieut. Theodore Owens, A. C., U. S. N., Naval Air Station, Hampton Roads, Va., survives him. He is also survived by his mother Mrs. Mary J. Owens, and a sister, Mrs. Mary J. Hansberger, both of Sedalia, Mo., and two brothers, Will M. and Fred J. Owens, of Atlanta, Ga.

Mr. Owens was elected a Member of the American Society of Civil Engineers on March 6th, 1889.

LOGAN WALLER PAGE, M. Am. Soc. C. E.*

DIED DECEMBER 9TH, 1918.

Logan Waller Page, born at Richmond, Va., on January 10th, 1870, came from a family distinguished in the public affairs of his State from the early days of the Jamestown Colony. He was a cousin of the late Walter Hines Page, recently Ambassador to Great Britain, and of Thomas Nelson Page, Ambassador to Italy, and a near relative of Dr. Thomas Walker Page, Chairman of the United States Tariff Commission. His technical education was obtained at the Virginia Polytechnic Institute and the Lawrence Scientific School of Harvard University. The late Nathaniel S. Shaler, his uncle, was Professor of Geology at Harvard University, and being a man who delighted in utilizing scientific knowledge for practical purposes, he became a strong advocate of a thorough scientific investigation of road-building materials and their correct use in highway construction. To put his ideas into effect, Professor Shaler, as Chairman of the Massachusetts Highway Commission, made Mr. Page its Geologist and Testing Engineer, in 1893.

As the Geologist of the Massachusetts Highway Commission, Mr. Page made the first extensive scientific investigation of road-building materials conducted in America. Although previous investigators had furnished information of value to road builders, it had been acquired incidentally to other geologic work. Mr. Page also inaugurated the petrographic study of these road-building materials, for the purpose of determining the relation between the composition of rocks and their behavior under traffic. In these early studies he demonstrated his possession of that rare scientific patience essential in order to discover the reasons for many of the empirical practices of engineering, which open a way for the rational improvement of older methods. The first comprehensive report on the constituents of road-building rocks which was printed in the United States was prepared by him in 1898. Some years later, in conjunction with Dr. E. C. E. Lord, he elaborated the programme of petrographic study of road-building materials which has been continued under his direction for many years, and about two years ago, with Dr. G. E. Ladd, he inaugurated a study of those features of economic geology which must be investigated scientifically in order to put road-stone quarrying on a satisfactory basis, both scientifically and practically.

The physical properties of rocks which affect their usefulness for road-building had been investigated by the French Bridge and Highway

* Memoir prepared by John M. Goodell, Assoc. Am. Soc. C. E., H. K. Bishop, M. Am. Soc. C. E., and T. Warren Allen, M. Am. Soc. C. E.

Corps for about twenty years when the Massachusetts Highway Commission undertook the same work. The French engineers had developed the Deval machine for testing the resistance to wear of rocks, the Dorry machine for testing hardness, and a machine for testing resistance to impact. Specimens of such apparatus had been used to some extent in the Massachusetts Institute of Technology, but it was not until Mr. Page introduced and improved the machines in the laboratory of the Massachusetts Highway Commission that physical tests of road-building rocks were regularly conducted as part of the routine work of a highway department in America. This step was taken in 1893. The Deval apparatus has remained in use with little modification since it was first introduced in France. The Dorry test is no longer used to any extent. Tests of the binding property of rock dust and of the toughness of rock were developed by Mr. Page for the Massachusetts Laboratory and subsequently improved under his direction in his laboratory at Washington. It might be added that the principles of the Page impact machine have recently been found useful in testing explosives. In these days, when such tests are carried on regularly in many laboratories, the part played by Mr. Page in introducing and improving them is likely to be forgotten.

In 1894 the United States Department of Agriculture had organized, under a $10 000 appropriation, an Office of Road Inquiry, mainly devoted to statistical and economic investigations. About 1899 Dr. Shaler discussed, with Secretary Wilson of the Department, the importance of conducting on a national scale the scientific study of road-building materials inaugurated by the Massachusetts Highway Commission. As the researches recommended by Dr. Shaler required laboratory facilities not possessed by the Office of Road Inquiry, Mr. Page, in 1900, was invited to become Chief of a Division of Tests in the Bureau of Chemistry. Here, with the assistance of Dr. A. S. Cushman, he inaugurated the series of scientific investigations which have since won international fame for the laboratories under his direction. These scientific investigations were later developed and extended under his direction, so that to-day they cover, not only the materials of road-building, but also the allied fields of research in which greater knowledge is enabling highway engineers to use more economically the money spent under their direction.

In the course of his studies of road materials, first in Massachusetts and later in Washington, Mr. Page acquired an intimate knowledge of road-building. After moving to Washington his engineering knowledge and firm grasp of the essential features of highway economics gradually won such recognition that Secretary Wilson consolidated all branches of the highway work under his direction in the Office of Public Roads, with Mr. Page as Director. This was in 1905, and, from a very small beginning, the work of the Office of Public Roads has developed and

extended until, at his death, his bureau was co-operating in road construction with every State.

In the early days of his directorship, Mr. Page found it necessary to visit many parts of the country, and to discuss the desirability and proper character of road improvement programmes for many different conditions. The importance of this work impressed him so strongly that in 1910 he secured the co-operation of a number of prominent men, among them the late Alfred Noble, Past-President, Am. Soc. C. E., in founding the American Highway Association, which conducted an active educational campaign for rational road improvements as long as such work was necessary. The organization of this Association and the useful work it did are proofs of the resourcefulness shown by Mr. Page in carrying out his plans for the betterment of the country's highways.

For many years he was engaged in two distinct lines of road work, educational and research. Under his direction, lectures on road topics were given in all sections of the country, good-road demonstration trains were run on many railroads, and numerous bulletins on the value, construction, and maintenance of roads were published. The value of this pioneer work done by the Department of Agriculture can be seen in the practically universal recognition of the importance of good roads. Where the conditions warranted it, special advice was given to communities contemplating the inauguration of highway betterments, in order that these scattered examples of good administration and good engineering would serve as models for other communities. In some cases actual demonstrations of the best methods of construction and maintenance were made. Later, when the drainage, irrigation, and rural engineering work of the Department of Agriculture were put under his direction, in 1915, the same general system was followed with these branches. The organization at this time became the Office of Public Roads and Rural Engineering, and later simply the Bureau of Public Roads.

The research work conducted under Mr. Page's direction embraced, not only laboratory investigations, but also service tests with experimental roads. The latter have been built in many parts of the country, with numerous types of construction. The service to which they are subjected is determined accurately and frequently, and in this way the facts regarding disputed features and materials of road-building have been ascertained. Then, by comparing laboratory and service results, the two are correlated, and furnish a guide for further investigations. This nation-wide research is now having one interesting result in a decided tendency toward the standardization of specifications for road materials. The work not only embraced the construction of roads, but also included their maintenance, a subject always uppermost in Mr. Page's mind, on account of its great financial importance. It

should be added here, that, on the advent of the automobile and the early indications of its destructive influence on roads, Mr. Page made a very careful investigation of the nature of this wear, and published both popular articles and technical papers advocating more durable forms of construction in order to meet the new conditions of travel.

Mr. Page's active participation in Federal road-building began in 1912, when Congress appropriated $500 000 for improving certain post roads. In 1916 Congress voted to give $75 000 000 to help road-building in the various States on a co-operative basis, the States providing at least an equal amount. The administration of this work was placed with the Secretary of Agriculture, who delegated the direction of it to Mr. Page. It was a new venture, and the early proceedings were complicated by delays incident to the necessity of obtaining legal approval of many of the administrative methods, and legal interpretation of various parts of the law. These delays caused some criticism, but, as time passed, the wisdom of proceeding in strict conformity with the law became apparent, and the great National value of Federal aid in road-building became clear. At the time this memoir is prepared, Congress has before it a bill to increase substantially the Federal appropriations for such work.

One of the most conspicuous examples of Mr. Page's foresight in matters affecting road work occurred after the United States took up arms. The congestion of the railroads led to the first drastic action restricting road-building, namely, an order forbidding the use of open-top cars for hauling road materials. Mr. Page obtained a modification of that order. Somewhat later, an order was issued forbidding the use of bituminous materials for road work. Mr. Page had this modified, after considerable difficulty. At his request, the Secretary of Agriculture then invited the Government departments and agencies affected in any way by road work to join with him in establishing a United States Highways Council to exercise control over the road work of the country during the period of the war. As a result of this invitation, the Highways Council was formed, and the allocation of available road materials and their transportation, and the approval of capital issues for road work were passed upon by a single body, which was able to assist road work, so far as the war programme made this possible. Mr. Page was the Chairman of the United States Highways Council, and the Bureau of Public Roads furnished most of the facilities and personnel for its work.

Before the administrative duties of the Bureau of Public Roads became so heavy as to demand most of his time, Mr. Page wrote numerous papers on subjects connected with road building, one of which, on oil-concrete, was contributed to this Society.* He was the

* "Some of the Properties of Oil-Mixed Portland Cement Mortar and Concrete", *Transactions*, Am. Soc. C. E., Vol. LXXIV (1911), p. 225.

author of "Roads, Paths, and Bridges," a non-technical discussion which had a wide circulation.

He was a man of strong, forceful personality, dominated by an unusually constructive imagination. He could develop a plan mentally and carry its main features in his mind without any apparent effort or gradual loss of clearness. This was a great gift for a Federal bureau chief, as it enabled him to pick up from time to time the materials and men needed to carry out an undertaking which would only become practicable when the resources for it were available. It was this planning far ahead which led many to regard him as idealistic; it was not dreaming, however, but an unusual faculty for preparing to meet the demands on his bureau, which he knew would be made later. It was this characteristic, furthermore, which made the research work under his direction very largely pioneer work, and gave the laboratories of the Bureau of Public Roads the unique place they occupy to-day.

Mr. Page was elected a Member of the American Society of Civil Engineers on July 1st, 1909.

MYRON HALL PECK, M. Am. Soc. C. E.*

DIED OCTOBER 9TH, 1918.

Myron Hall Peck was born at Racine, Wis., on October 13th, 1876. He was the son of Dr. Albert P. and Celia Flagg Peck. His father served in the Civil War, although he was only 17 at the time of his enlistment. In 1880, the family moved to Shantung Province, China, where Dr. Peck was a medical missionary under the American Board of Commissioners for Foreign Missions—the Congregational organization—for more than 20 years, and Myron Hall Peck's boyhood was spent in China and in California. He was graduated from the College of Civil Engineering at the University of California with the Class of 1897, with the degree of B. S.

After graduation, he engaged in civil engineering and mining work in various parts of California until 1902, when he returned to China to become Professor of Civil Engineering in the Chinese Imperial University in Shansi and, later, at the Imperial Pei Yang University at Tientsin, which position he held until he came back to the United States in 1911.

Mr. Peck's first work after his return was for the War Department, on the improvement of the bar at the mouth of the Columbia River. Following this, he went to San Francisco, where he opened engineering offices, which he maintained most of the time until 1916. During part of this time, he was engaged as Engineer in Charge of the improvement of the channel at Mare Island Navy Yard, for the Standard American Dredging Company, the contractors doing the work.

In 1916, he enlisted in Company A of the Engineer Corps of the California National Guard, and served as Second Lieutenant during the Mexican Border troubles, being stationed most of the time at Nogales, Ariz. By special arrangement, he was mustered out of the service in December, 1916, at the request of the Citizens' Committee of Vallejo, Cal., in order that he might prepare a report on channel conditions and other factors which might influence the possible enlargement of the Mare Island Navy Yard, the Committee recognizing that his experience in connection with the improvement of the channel made him particularly fitted for this work. Later, he went to Washington on behalf of the Committee.

Soon after the Engineer Officers' Reserve Corps was created, Mr. Peck applied for a commission, and was assigned for training to Camp Lee, Va., early in 1917. He was commissioned a Captain and spent several months in training troops at Camp Lee. In January, 1918, he sailed for France. Then followed a brief period of further work back of the lines, but the last few months of his life were mainly spent

* Memoir prepared by A. T. Parsons, Assoc. M. Am. Soc. C. E.

at the front with the Second Division, commanded by Major-General John A. Lejeune. Captain Peck was at Chateau Thierry, St. Mihiel, and in many less known engagements. During a large part of the time he acted as Battalion Commander, his untimely death doubtless preventing his promotion to the rank of Major.

On October 9th, just after he had led his battalion through a particularly brilliant action near St. Etienne-a-Armes, which won for him the posthumous honor of the Distinguished Service Cross, Captain Peck was struck by a fragment of shell and killed instantly.

No better idea of the stuff of which Captain Peck was made, as well as the circumstances of his death, can be given than by quoting from the following letters, the first being from the First Sergeant of his Company:

"At 8 A. M., October 9th, we were being attacked and the 'boche' put over a murderous barrage. Captain Peck was standing in the cemetery, which we occupied and regarded as our strong point, directing his men. He seemed oblivious to all danger and fell in the performance of his duty. * * *

"This regiment has suffered a severe loss, as the late Captain was a model soldier and gentleman in every respect. As my company commander, I had been on several reconnaissance and other details with him, and I learned to admire his soldierly ability and gentlemanly qualities. In fact, I felt perfectly safe in following Captain Peck anywhere, and I lost a close friend when death called him away.

"JOHN D. DRURY,

"First Sergeant, Company E, Second Engineers."

The second extract is from a letter from the Colonel of his Regiment:

"Captain Peck was killed in action during particularly difficult fighting. His death came directly as a result of his fearless exposure of himself in doing his duty. He was beloved by his men for his personality, his qualities of leadership, and his apparent fearlessness.

"His body was immediately recovered by his comrades, and as carefully buried as was possible under existing circumstances. Later, it was removed to a French cemetery. * * * The headstone was carved by one of his men, who did all the carving with a pocket-knife. It was a labor of love. * * *

"His efficiency was becoming increasingly evident, and he would soon have been made a Major. In fact, he had been actually commanding the battalion for two months.

"W. A. MITCHELL,

"Colonel, Second Engineers."

Although these letters do justice to the gallant soldier who has gone from us, they do not give a complete idea of the capable engineer and the true friend it was a privilege to know.

Captain Peck was a charter member of the Engineers' Club of San Francisco, having served as Vice-President during the year following its founding in 1912.

In 1905, Captain Peck was married to Miss Mary Moore, who, with two children, Gladys Logan and Albert Carlton Peck, survives him. He is also survived by his parents, Dr. and Mrs. A. P. Peck, of Tientsin, China, by two brothers, Willys R. Peck, U. S. Consul at Tsing-Tao, China, and Llewellyn B. Peck, of San Francisco, Cal., Second Lieutenant in the Aviation Section, Signal Reserve Corps, U. S. Army, and one sister, Mrs. Thomas T. Read, of Montclair, N. J.

Captain Peck was elected an Associate Member of the American Society of Civil Engineers on January 5th, 1909, and a Member on March 14th, 1916.

JOHN HOWE PEYTON, M. Am. Soc. C. E.*

DIED SEPTEMBER 14TH, 1918.

John Howe Peyton was the fourth son of William Preston Peyton, of Montgomery County, Virginia, and Sarah Elizabeth (Mumford) Peyton of Richmond, Va. His paternal grandfather, Major Garnet Peyton, was in active service in the United States Army during the War of 1812. His maternal grandfather was a man of great literary ability, whose chief work was the translation of Homer's Iliad into blank verse. John Howe Peyton was born in Howard County, Missouri, on March 17th, 1864, his parents having thought to make their future home there, but returned to Virginia soon after the close of the Civil War. His family, like many others, suffered many hardships as a result of the war, but his father succeeded in giving each of his five sons a college education. In December, 1873, the family moved to Salem, Va., and he entered the Preparatory Department of Roanoke College, finishing his course in 1881.

At that time railroad construction and surveys were active, and Mr. Peyton joined one of the engineering parties of the Richmond and Louisville Railroad, a project which was then being pushed.

In 1883 he was Instrumentman for the Farmville and Powhattan Railroad, and from 1885 to 1888 he was Resident Engineer on construction for the Lynchburg and Durham Railroad, later holding a similar position with the Georgia, Carolina and Northern Railway. From 1889 to 1891 he was Assistant to the Chief Engineer of the Charleston, Clendenning and Sutton Railroad.

From 1892 to 1898 Mr. Peyton engaged in private practice as an Engineer and in contracting, having his office at Charleston, W. Va. In 1899 he joined the United States Army, and became a Sergeant in the Engineer Corps, and, later in the year, went to the Philippines as special representative of the Protestant Episcopal Church.

From 1900 to 1901 he was Resident Engineer of the Chesapeake and Ohio Railroad, and, later, was made Chief Engineer of the Great Eastern Railroad, serving in that capacity until 1902, when he entered the service of the Louisville and Nashville Railroad Company as Locating Engineer. His work for this company consisted of surveys and estimates for extensions, and for reducing grades on their existing lines. He at that time located the revision of the line and grade of the Henderson Division, between Edgefield Junction and Hygeia, where a 4% grade was replaced with a 0.7% grade, requiring very heavy work and a tunnel about 4 000 ft. long. He also located the Atlanta, Knoxville and Northern Railway, from Etowah, Tenn., to a junction

* Memoir prepared by Hunter McDonald, Past-President, Am. Soc. C. E.

with the Western and Atlantic Railroad, at Junta, Ga. He was placed in charge of the construction of these two lines, but was made Principal Locating Engineer for the company in 1904, and served in that capacity until 1907.

After the panic of 1907, Mr. Peyton left the service of the Louisville and Nashville Railroad Company, and accepted a position with the Union Pacific Railroad in the Northwest, making investigations in Montana, Washington, Oregon, and British Columbia. He returned to the service of the Louisville and Nashville Railroad Company in 1910 as Assistant to the President.

In March, 1912, he was made Chief Engineer of Construction, and carried the title of Assistant to the President and Chief Engineer of Construction, Louisville and Nashville Railroad Company. His duties consisted of locating and superintending the construction of a number of very heavy pieces of grade reduction and extension work, notably the Lewisburg and Northern, extending from Portland, Tenn., to Decatur, Ala., the revision of the South and North Alabama Railroad, between Decatur and Birmingham, the Lexington and Eastern Railroad, an extension from Covington, Ky., into the coal fields of Eastern Kentucky, and the Tuscaloosa Mineral Railway.

In January, 1914, Mr. Peyton was appointed General Manager and, in April following, President of the Nashville, Chattanooga and St. Louis Railway Company. He assumed the duties of these offices with preconceived ideas of the obligations of the railroads to the public, and entered at once into a vigorous campaign to put these ideas into effect.

He traveled over the lines of road on trains and in motor cars, studying location and grade-reduction problems, and, where his view from the train was circumscribed, he made many trips in automobiles through the mountains, studying the topography. He organized surveying parties, appointed a Superintendent of Construction, and personally directed the work. He revised the existing schemes for grade reduction between Sherwood, Tenn., and Paducah, Ky., by way of Nashville and Hollow Rock Junction.

During his term of office a considerable portion of this work was begun, some of it was executed, but the breaking out of the war with Germany compelled the stoppage of most of it. However, pending the completion of the grade-reduction plan, the tonnage of trains was greatly increased by the purchase of larger engines and the use of helping engines at points where they had not been utilized previously.

Mr. Peyton organized an Agricultural Department of the Railway, bought demonstration farms in a number of counties, established modern farming methods thereon, and, under the direction of a Special Agricultural Agent, these farms were instrumental in greatly improving

farming methods throughout the South. He made many trips over the road, speaking to citizens and at Farmers' Institute meetings.

On the assumption of control of the railroad by the Government, Mr. Peyton was called on to make several studies for the Regional Director of the Southern Region, and reported on the navigation scheme on the Mississippi River between St. Louis and New Orleans, and on the Black Warrior River from the coal fields of Alabama to Mobile and New Orleans. He was peculiarly fitted for this assignment, having previously made a study of inland navigation and written a book, entitled "The American Transportation Problem", which dealt particularly with comparisons between railway and inland transportation by water.

Before he assumed the Presidency of the Railway, the project of building the Paducah and Illinois Railroad, which included a bridge over the Ohio River at Metropolis, Ill., had taken shape, and work had begun, but, on the breaking out of the war, it was stopped. Mr. Peyton succeeded in re-organizing the work, and, through his efforts, it was brought to a successful conclusion, under the direction of C. H. Cartlidge, M. Am. Soc. C. E., Bridge Engineer of the Chicago, Burlington and Quincy Railroad, and Chief Engineer of the Paducah and Illinois Railroad, who, however, died before the bridge was entirely completed.

Mr. Peyton did not remain with the Nashville, Chattanooga and St. Louis Railway under Federal control, but retained the Presidency of the Corporation. Just prior to this change, however, he undertook, for the railway, the construction of the Old Hickory Powder Spur for the United States Government, which was completed in a remarkably short time. After the institution of Federal control of the railways, Mr. Peyton made application for a Commission in the Engineering Corps, desiring to enter the American Expeditionary Forces.

Mr. Peyton was a very devout member and lay-reader of the Protestant Episcopal Church. He was a Trustee of the University of the South, an Episcopal School, at Sewanee, Tenn., of George Peabody College for Teachers, at Nashville, Tenn., a Director in the Andrew Jackson Memorial Association, in the Monteagle Assembly and Summer School, and in the Southern Howard Association, and was active in all.

He was President of the Nashville Section of the Engineering Association of the South in 1916, was a Member of the American Railway Engineering Association, of the Tennessee Historical Society, and the Tennessee Academy of Science. He was also a Member of the Old Oak Club, the Rotary Club, the Hermitage Club, and the Commercial Club, in Nashville.

He was intensely public-spirited, religious, and charitable, devoting much of his time and money to these causes.

Mr. Peyton came of ancestors who were distinguished for their statesmanship and service to the State of Virginia and the Nation. He was very proud of Virginia, and took a deep interest in her welfare and in the welfare of the South. He was especially devoted to young men, and attached many of them to him through his kindness and consideration for their advancement. It was always a source of regret to him that his parents made their excursion to Missouri, and of joy that they returned to their beloved Virginia after so short a stay in the West.

Mr. Peyton was never married. His death occurred at his home on West End Avenue, in Nashville, Tenn., on the morning of September 14th, 1918. Two elder sisters, Misses Elizabeth M. and Sallie R., survive him, with their nephew, Wythe M. Peyton, who resides near Jennings, Va. There are also two elder brothers, William M. Peyton, of Martinville, Va., and Carlton P. Peyton, of Charleston, W. Va. His other nephew, the Rev. William P. Peyton, served with the American Expeditionary Forces in France.

Mr. Peyton was elected a Member of the American Society of Civil Engineers on June 1st, 1909.

ROBERT WINTHROP PRATT, M. Am. Soc. C. E.*

DIED FEBRUARY 2D, 1920.

Robert Winthrop Pratt was born on December 23d, 1876, in Brookline, Mass. He was descended from old New England families, his father—a descendant of John Alden—being Robert Winthrop Pratt, and his mother, Grace (Kellogg), Pratt.

Mr. Pratt's early education was obtained in the public schools of Boston, while his technical education was acquired at the Massachusetts Institute of Technology, from which he was graduated as a Civil Engineer in 1896.

After his graduation, Mr. Pratt began his practical engineering experience with the Boston and Albany Railroad. After about a year of railroad work, he left this field and started his career in sanitary engineering as Assistant Engineer with the Massachusetts State Board of Health. He remained with the State Board of Health for four years and then moved to Ohio, where he was engaged as Chief Engineer of the Ohio State Board of Health, holding this position from 1903 to 1911. During the early years of his work in Ohio, he also supervised for the Federal Government the gauging of stream flows in Ohio streams. This work was well performed and has proved to be of considerable value.

During one year of his connection with the Ohio Board of Health, namely 1909-10, Mr. Pratt was given a leave of absence to permit him to visit Havana as Consulting Engineer for the Cuban Government, in connection with the design of water supply and sewerage systems for several Cuban cities.

In October, 1911, Mr. Pratt left his position with the State Board of Health and moved to Cleveland, Ohio, where he became Special Sanitary Engineer for the latter city, and where he also began his private practice as Consulting Sanitary Engineer.

In connection with his work in Cleveland, he directed the tests and investigations which were conducted preliminary to designing the sewage disposal plants for the city. The early studies and general plans for the Cleveland Sewage Disposal System were also carried on under Mr. Pratt's general direction. During this same period, he also acted as Consulting Engineer for the Water Department, in connection with the design of the water filtration plant.

Mr. Pratt's professional life was an exceedingly busy one, and many places in Ohio and elsewhere are supplied with sewerage or water systems and with treatment plants built under his direction. He had also

* Memoir prepared by Robert Hoffmann and W. H. Dittoe, Members, Am. Soc. C. E.

prepared a number of important reports on water and sewerage projects, of which the preliminary studies and report on the Toledo, Ohio, sewerage problem and his investigation, tests, and report on the proposed filtration of the water supply of Detroit, Mich., may be mentioned as of special importance.

The World War found Mr. Pratt particularly busy in connection with engineering work for the Chillicothe Cantonment and with industrial housing developments.

He had prepared many printed reports in connection with his Board of Health work as well as descriptions of work designed by himself. He was joint author of the well-known book on "Sewage Disposal", by Messrs. L. P. Kinnicut, C.-E. A. Winslow, and R. Winthrop Pratt.

Mr. Pratt had a fine, pleasing personality and was a most agreeable associate, socially and in business. He had a faculty of taking a broad view of things which helped him wonderfully in matters coming to his attention. He had high ideals of engineering ethics which he practiced himself and expected others to observe. Through his untimely death, which was due to pneumonia and occurred on February 2d, 1920, after only a week's illness, the Engineering Profession loses a valued member and his closer acquaintances a true and faithful friend.

In June, 1903, he was married to Elizabeth Southwick, of New York City, who, with a family of two sons and two daughters, survives him.

Mr. Pratt was elected a Member of the American Society of Civil Engineers on June 6th, 1911.

HOMER PETER RITTER, M. Am. Soc. C. E.*

DIED APRIL 21ST, 1919.

Homer Peter Ritter was born in Cleveland, Ohio, on March 4th, 1855, and received his early education in the schools of his native city. On being graduated from the Cleveland High School, guided by an artistic temperament which was a marked characteristic through life, he entered the Cincinnati School of Design, but, after a short stay, withdrew from this institution and matriculated in the School of Mines, Columbia University, New York City. At Columbia he selected a special course in Civil Engineering, and, on its conclusion, in 1880, received an appointment in the service of the Mississippi River Commission and was at once assigned to the field. As the Commission was organized in 1879, Mr. Ritter was one of its first employees, and, in the five years between 1880 and 1885, was engaged as Assistant United States Engineer in the topographic and physical hydrographic operations on which were based the comprehensive plans for the regulation of the great river.

In 1885, Mr. Ritter was transferred to the U. S. Coast and Geodetic Survey, for employment in the physical hydrographic surveys and examinations, under Professor Henry Mitchell, that were a necessary antecedent for the improvements that have met the demand for the modernization of the waterways about New York City; and, later, on similar surveys in the waters adjacent to Boston and off the New England Coast; and on general hydrographic and topographic work of the Survey. In 1893 he was appointed American representative in a Canadian photo-topographic party that formed a unit in a group of American and Canadian parties which initiated the exploratory surveys and maps used by the Alaskan Boundary Tribunal in laying down the line of delimitation between the United States and British possessions between Mt. St. Elias and the Portland Canal.

In 1895, Capt. Ritter was appointed Assistant in the normal force of the Coast and Geodetic Survey, a designation of rank which was changed to that of Hydrographic and Geodetic Engineer in 1917. From 1898 to 1904 his work was confined entirely to the Pacific Coast, and included a large portion of the range of duties covered by the Survey. In 1898 his services included magnetic and astronomical operations in California and Nevada; from 1899 to 1903, in command of the U. S. Coast and Geodetic Survey steamer *Taku*, he was employed on triangulation, hydrography, and topography in Controller Bay, Prince William Sound, and about Kodiak Island; and in 1904 he commanded the U. S. Coast and Geodetic Survey steamer *McArthur*

* Memoir prepared by R. I. Faris, M. Am. Soc. C. E.

engaged in special surveys about Kiska, one of the extreme western islands of the Aleutian Group.

In 1904, Capt. Ritter, on nomination by President Roosevelt, was confirmed by the Senate as a member of the Mississippi River Commission, thereby renewing his connection with the body which he had entered at the beginning of his professional career, and in which he was destined to render his last service, for it was from a regular trip of inspection of the Commission that he returned incapacitated by the illness which caused his death within four days after his return to his home in Washington, D. C.

In 1904, Capt. Ritter was transferred from duty on the Pacific Coast to the Coast and Geodetic Survey Office in Washington, D. C., and the remainder of his services were rendered on the Atlantic Coast, and, in the interval between the beginning of 1905 and his death on April 21st, 1919, these were of a greatly varied and highly valuable character. Besides his active employment for 15 years as a member of the Mississippi River Commission, he was engaged as a member on the 14-ft. Waterway Board; completed a thorough physical hydrographic survey of the Potomac River, in connection with the determination of the causes and correction of its pollution; repeatedly was assigned to determine and locate speed courses for the Navy; make extensive resurveys for chart revision in Chesapeake Bay, Long Island Sound, and along the coast of Massachusetts; and conducted an extensive triangulation in North Carolina. His last assignment to duty in the Coast and Geodetic Survey was to the position of Inspector in Charge of the U. S. Coast and Geodetic Survey Field Station at Boston, Mass., and during this incumbency, which continued to the day of his death, he was conducting revision surveys along the Massachusetts Coast.

Capt. Ritter was a man of unostentatious but admirable qualities, and especially distinguished by a rare type of humor which was blended with a singular knowledge of humanity and a depth of sympathy that seemed unfathomable. It is related of him that when but little more than a youth, during one of the great floods in the Lower Mississippi, in the face of a danger that forbade others to adventure it, he went, alone, in a dugout, to the rescue of an unfortunate negro who, marooned on the roof of a cabin, was being hurried to destruction by the raging river, and brought the man to safety. At another time he and one companion, during an outbreak of fever, resisting the fear that drove off their other well companions in panic, abided with those stricken down by the disease until all danger from contagion had passed and medical assistance could be brought to them.

At a meeting of the Mississippi River Commission on April 23d, 1919, the following resolution on the death of Capt. Ritter was presented by J. A. Ockerson, Past-President, Am. Soc. C. E., and carried:

"An all wise Providence has suddenly called from our midst our friend and associate Homer P. Ritter, and we desire to spread upon the records of the Mississippi River Commission this statement of the deep sorrow which has fallen upon us without warning and expressions of our sympathy for his family with whom we mourn his loss.

"He entered the work of the Commission in 1879 and rendered valuable aid in the physical investigations of the Mississippi River. After serving six years in that capacity he was called to the service of the Coast and Geodetic Survey where he was still a prominent member of its corps of experts when he came to his untimely end.

"He was appointed a member of the Mississippi River Commission in 1904, and his conscientious devotion to duty was such that although ill he insisted on accompanying the Commission on its inspection trip leaving St. Louis on April 15, 1919, but on reaching Memphis, April 17, illness compelled his return to his home in Washington, and he bade us a sad farewell.

"He will linger with us in fond remembrance for his kindly, genial friendship and his good qualities as a valuable Member of the Commission.

"As a matter of respect to his memory, be it resolved that the flag on the steamer *Mississippi* be carried at half mast during the present session of the Commission."

Capt. Ritter was married on April 12th, 1912, to Miss Katherine R. Wagner, of Piqua, Ohio, and, besides his widow, is survived by two brothers and two sisters. He had been a member of the Cosmos Club of Washington since 1892.

Capt. Ritter was elected a Member of the American Society of Civil Engineers on November 3d, 1915.

ALBERT ALONZO ROBINSON, M. Am. Soc. C. E.*

DIED OCTOBER 7TH, 1918.

Albert Alonzo Robinson was born in the little Village of South Reading, Vt., on October 21st, 1844. He was a son of Ebenezer Robinson, Jr., and Adelaide (Williams) Robinson. For generations his ancestors had been New Englanders. His grandfather, Ebenezer Robinson, fought in the Revolutionary War. His father, Ebenezer, Jr., was a country school teacher, farmer, and carpenter. He was a mechanic of no mean ability, and the talent he possessed was passed on to his three sons, all of whom have been more than successful in the particular line of engineering in which they embarked. He died in 1848, leaving his wife with a family of four children. Five years after the death of her husband, she married Mr. Albert Childs, and the family moved West, where Mr. Robinson was to stamp the mark of his genius on the country by constructing a great railway system. Although he was held down by the necessity of work and the hardships usually faced by the pioneer Westerners, he received a college education. He attended the Academy at Wilton, Wis., after finishing the common school course, and, later, entered the University of Michigan, from which he received the degrees of Bachelor of Science and Civil Engineer, in 1869. In 1871 his Alma Mater conferred on him the degree of Master of Science, and, in 1900, further honored him with the degree of Doctor of Laws.

Relative to Mr. Robinson's early life: From childhood until he reached his majority he was employed in farm labor, except for a short period when he worked as a clerk in a grocery and dry goods store. While he was a student at the University of Michigan, he was occupied for about five months every year as an Assistant Engineer on the United States Lake Survey in astronomical and field work and in the triangulation of the Great Lakes.

His railroad work began in 1869, when he entered the service of the St. Joseph and Denver City Railroad. Mr. Robinson was actively engaged in work with the railroads of the West for a period of 37 years, and rose, by successive promotions, to be Vice-President of the Santa Fé and President of the Mexican Central Railway. It was in April, 1871, that Mr. Robinson entered the service of the Santa Fé, which road was then scarcely 100 miles long. When he left, 22 years later, it had grown into a system of more than 9 000 miles, more than half of which had been built by him.

Mr. Robinson's first work with the Santa Fé was on surveys and construction, between Topeka and Atchison. He was made Chief

* Memoir prepared by J. M. Meade, Esq., Special Engineer, Atchison, Topeka and Santa Fé Railroad, Topeka, Kans.

Engineer in 1873, and, later, held the following positions, in the succession in which they are given: Division Superintendent; Superintendent of Bridges, Buildings, and Water Service; Assistant General Superintendent; General Manager; Second Vice-President; Vice-President and General Manager.

In 1893 he resigned to become President of the Mexican Central Railroad, which position he held until his retirement in 1906, because of his advanced age and the state of his health. While he was President of the Mexican Central, his office was in Boston, Mass. He proved himself a very able administrator, as well as a great engineer, and developed that road into a great railway system. When he went to the Mexican Central, the stock of that company was selling at 5 cents a share and the bonds at 43 cents a share. When he retired, the stock was selling at 50 cents and bonds at 80 cents.

Having built between 5 000 and 6 000 miles of railroad, Mr. Robinson was known as one of the world's greatest civil engineers. The present lines of the Santa Fé Railroad were all constructed under his direction. Coming to the Santa Fé in 1871, he laid out hundreds of miles of that fast-growing railroad. As Chief Engineer, he outlined and executed the vast building operations, conceived and effected by Messrs. C. K. Holliday and W. B. Strong. As General Manager, it was his keen judgment that drew hundreds of men to the Santa Fé, and made it the leader of the railroads of the country. He was a leader who was loyal to his men; although twenty years have passed since he was connected with the Santa Fé, his name will go down in the history of that System, as an honest, loyal, staunch friend of his fellow workers.

Mr. Robinson was married in 1869 to Julia Caroline Burdick, of Edgerton, Wis., who died in August, 1881, leaving a daughter, Metta Burdick. On September 2d, 1885, he was married to Mrs. Frances Williams, a sister of his first wife, who, with his daughter and a granddaughter, survives him.

Mr. Robinson was one of Topeka's best known and respected citizens. His residence in that city, since 1875, after a period of nearly 40 years of railroad activity, speaks eloquently of his faith in the city's future and his high esteem of its citizenship. He had always taken a prominent part in local as well as National affairs, and was Past-President of the Topeka Chamber of Commerce, as well as a prominent member of many other local and civic organizations. In politics he was a Republican, and was always connected with the better things associated with the affairs of the city and country.

In 1876 he erected one of the grand residences of Topeka, which is known as one of the beauty spots of Kansas. His home contains one of the greatest collections of art in the West.

Mr. Robinson's death occurred on October 7th, 1918, after months of sickness, which had caused most of his close friends and relatives to lose hope of his recovery.

He was a member of many famous and exclusive civil, technical and social societies, among which were the Topeka Club, the Country Club, the Chicago Club of Chicago, Ill., the Lawyers Club of New York City, and the Jockey and University Clubs of the City of Mexico.

Mr. Robinson was elected a Member of the American Society of Civil Engineers on May 5th, 1880.

JOHN WARREN SACKETT, M. Am. Soc. C. E.*

DIED JULY 3d, 1918.

John Warren Sackett was born at Rantoul, Ill., on December 13th, 1860. He received his elementary education at that place, and when he was 14 years old, he had been graduated from the High School and had passed the entrance examinations to the University of Illinois. He was prohibited from entering at that time, however, by reason of the age limit—15 years—in force there. In 1876 he became a student in the Civil Engineering Department of the University where he remained for two years. He also took manual training in carpentry and machine work.

In 1877 and 1878, Mr. Sackett taught school, with the intention of completing his college course, but his father, who had moved to Florida and was engaged in contracting and building, required his services in his business. In this connection Mr. Sackett made architectural drawings and superintended construction work, as well as operating a saw-mill. In the meantime, he continued his engineering studies under J. Francis LeBaron, M. Am. Soc. C. E., by whom he was engaged in land and railroad surveying and in the operation of a short line of railroad, as well as on Government surveys of various canals, rivers, and harbors in Florida.

On May 16th, 1881, Mr. Sackett was appointed an Assistant Engineer in the United States Engineer Corps, by the late Col. Q. A. Gillmore, Corps of Engineers, U. S. A., M. Am. Soc. C. E., on the recommendation of Mr. LeBaron, U. S. Assistant Engineer, under whom he was serving, and was identified with that organization for more than thirty-five years, as follows:

May and June, 1881, he served as Recorder in the party of Mr. Le Baron, under whose immediate direction he remained, until 1886, on the survey for a canal route from the head-waters of the St. Johns River to Charlotte Harbor, Florida; December, 1881, and January, 1882, he was engaged as Inspector on jetty work at Cumberland Sound, Georgia, and Florida; about this time he entered a competitive examination for appointment to West Point Military Academy and had been recommended for entrance, but owing to political reasons, the appointment was not granted; until the fall of 1883, he was Inspector of jetty work at the entrance to St. Johns River, Florida; until the spring of 1884, he was engaged as Instrumentman on a survey of the Savannah River; in 1885, he made a survey and plans for a Marginal Railroad in Jacksonville, Fla., under the direction of Mr. LeBaron, Chief Engineer, and surveyed and platted several town sites; he also served,

* Memoir prepared from information furnished by J. Francis LeBaron, M. Am. Soc. C. E., and on file at the Headquarters of the Society.

until May, 1885, as Chief Draftsman in the Surveyor-General's Office at Tallahassee, Fla.; until February, 1886, he was Superintendent and Draftsman, under Capt. William T. Rossell, Corps of Engineers, U. S. A., on dredging and rock excavation at Tampa and Cedar Keys, Fla., and in the spring of the same year, he served as Assistant, under Capt., now Maj.-Gen., William M. Black, Corps of Engineers, U. S. A., M. Am. Soc. C. E., on the survey at the entrance to St. Johns River, Florida; and from that time until 1888, he was engaged as Assistant Engineer in charge of the survey at the northwest entrance at Key West Harbor, Florida, and of a survey of the Caloosahatchee River.

In 1888, Mr. Sackett was made Principal Assistant Engineer of the Florida District, and given general supervision of the details of the work in that District under the direction of the District Engineer Officer, continuing in that position until his sudden death on July 3d, 1918, his title having been changed in 1917 to that of Chief Assistant Engineer of the Florida District of the U. S. Engineer Department. His work as Principal and Chief Assistant Engineer of the District consisted in preparing plans, projects, estimates, reports, etc., for submission to the Chief of Engineers, as well as the detailed design construction, operation, maintenance, etc., of all the floating plant, such as hydraulic dredges, steam and power plants, hyacinth elevators, etc. In connection with this work, he had introduced many novel improvements in successful operation, on several of which patents have been issued.

While a student at the University of Illinois in 1876-77, Mr. Sackett had received some military training, and, in 1895, he was commissioned as Captain of Co. G, 1st Florida Infantry, known as the St. Augustine Rifles. When war with Spain was declared in 1898, Capt. Sackett was promoted to be Major in the 1st Florida U. S. Volunteer Infantry, but was afterward detached from that regiment and placed in command of a Provisional Engineer Battalion formed by details from Florida and Illinois troops. After training for about six weeks at Port Tampa, Fla., Maj. Sackett left there with the Battalion and arrived at Santiago, Cuba, the day following the surrender of the Spanish Forces. After some construction work at Guantanamo Harbor, the Battalion joined the Porto Rican Expedition and led the landing party at Guanico on July 25th, 1898, under fire, with Maj. Sackett in command of the right wing. For this action and for soldierly qualities displayed on the night of July 26th-27th, 1898, when on outpost duty, he received the brevet rank of Lieutenant Colonel, U. S. Volunteers, "for coolness under fire and efficient and meritorious services during the war."

Maj. Sackett remained with the Battalion until it was disbanded in New York City in September, 1898. He was not mustered out of service, however, until January, 1899, having been placed in command of a battalion of a Florida Regiment stationed at Huntsville, Ala.,

where he acted as Brigade Commander for a time, although only ranking as Major.

The following is an extract from the report of Col. Black, Chief Engineer, U. S. Volunteers, to the Adjutant General of the Army, dated August 22d, 1898, regarding the operations of the Battalion:

"For the drill, discipline and spirit, much credit is due the officers of the battalion, among whom discrimination cannot be made, excepting it be for the commanding officer, Major J. W. Sackett, 1st Fla. Vols., whom I have known for years as a valued civil engineer employee of the United States. It is but fair for me to say that, without his aid, I do not know how I could have performed the duties allotted to the Engineer force of the expedition."

After the war he rejoined the Florida Militia as Captain and was promoted through the various ranks until he was commissioned as Brigadier General of the Florida National Guard, on February 28th, 1906. Gen. Sackett was retired on February 22d, 1907, at his own request, due to press of work with the U. S. Engineer Department. During his service with the Florida Militia, he was a member of the Commission appointed to select a permanent camp site, personally located the site subsequently adopted by the State authorities, and until his death served on the Board which had charge of the grounds. He also supervised all the surveying and engineering work in connection with the development of the camp and target range, and prepared plans and estimates for its enlargement, water supply, etc. In 1917, when the United States entered the World War, Gen. Sackett immediately offered his services to the Adjutant General, U. S. Army, in any military capacity that would be useful.

On July 1st, 1918, in the line of duty, Gen. Sackett left St. Lucie Inlet, Fla., on board the dredge *Florida* bound for Jacksonville, where the boat was to be used in dredging operations at Camp Joseph E. Johnston then under construction. On the trip up the coast the dredge encountered a heavy gale. One of the bulkheads was stove in by a heavy wave on July 3d, 1918, and the *Florida* filled and sank within three minutes. Gen. Sackett, who was in the cabin on the upper deck at the time and, it is supposed, did not realize the danger, and two of the crew perished with the boat. He is survived by his widow and two sons, Arthur J. Sackett, Assoc. M. Am. Soc. C. E., and Guy W. Sackett.

Gen. Sackett was one of the best known and most popular men in Government work and military circles in Florida. He was held in high esteem by all who knew him, and his untimely death was a shock to his many associates and friends who were numbered by his acquaintances.

In the course of thirty years or more of service with the U. S. Engineer Department, he had been called on to investigate, discuss,

and make out in technical detail and report on hydrographical and topographical surveys, watersheds, run-off, stream flow, tidal currents, wave action, jetties, breakwaters, locks, etc. For the purpose of observation and study, he had visited the Panama Canal during its construction. He had also visited Havana, Cuba, for the purpose of observing the raising of the wreck of the U. S. S. *Maine*, as well as other works of improvement affecting waterways, drainage, and reclamation work throughout the United States.

As shown by his military record, Gen. Sackett had been identified with the Florida State Militia for many years, and was Past Department Commander of the United Spanish War Veterans, Department of Florida. He was also prominent in Masonic and Elk circles, and other fraternal organizations.

Gen. Sackett was elected a Member of the American Society of Civil Engineers on May 2d, 1894.

HERMANN FREDERICK AUGUST SCHUSSLER, M. Am. Soc. C. E.*

DIED APRIL 27TH, 1919.

Hermann Frederick August Schussler was born in Rastede, Germany, on August 2d, 1842. He came to California from Europe in 1864, after having spent two years in the study of hydraulic and mechanical engineering at the Zurich, Switzerland, and Karlsruhe, Germany, Polytechnic Schools. He gained his first practical experience on engineering work during vacations, having been employed on railroad and bridge work at Lucerne, Switzerland, and as a Mechanical Draftsman at Bremen, Germany.

As early as October, 1864, Mr. Schussler entered the service of the Spring Valley Water-Works (now the Spring Valley Water Company) which supplies water to San Francisco, Cal. He was advanced to be Chief Engineer in 1866, and served in that capacity for 42 years, until 1908, when he was relieved from active charge; he was retained by the Company in an advisory capacity, and continued in private practice as a Consulting Engineer.

During his long connection with the Spring Valley Water Company, Mr. Schussler was more than Chief Engineer of the Company's system. It fell to him to forecast the future water requirements of San Francisco and to take such measures from time to time as would put the Company in a position to meet the constantly growing demand for water. One near-by source after another was added to the System and, by the acquisition of large areas of land in the water-sheds, tributary to the storage reservoirs on which the supply to the city is dependent, the quality of the water was safeguarded. Ownership of the water-sheds has made it a simple matter to police the areas in which pollution would otherwise be possible.

During his 42 years of active charge as Chief Engineer of the Spring Valley Water Company, Mr. Schussler designed and constructed all the works of the Company, the aggregate cost of which during that time reached about $20 000 000, and which include such notable achievements as the Crystal Springs Dam, a gravity section concrete structure, and a number of lines of riveted wrought-iron pipe, the service of which for 30 to 40 years, with only moderate deterioration, is most gratifying evidence of the care with which the material for their construction was selected and with which their construction was supervised.

As early as 1870, in the capacity of Consulting Engineer to a mining company, Mr. Schussler designed a 30-in. pipe line, an inverted siphon, more than 3 miles in length, across Feather River Canyon, the success of which went far to give engineers confidence in the use of riveted

* Memoir prepared by C. E. Grunsky, G. A. M. Elliott and F. C. Herrmann, Members, Am. Soc. C. E., a Committee of the San Francisco Section of the American Society of Civil Engineers.

wrought-iron pipe. He was Engineer for the La Grange Mining Company in 1871-72, constructing for this company the mining canal from near Dom Pedro Bar, on the Tuolumne River, to near La Grange; he made surveys and triangulations for the control of the alignment of the Sutro Drainage Tunnel; he constructed the earth dam for the Lagunitas Storage Reservoir in Marin County, California, as well as the 7-mile, 12-in. pipe line for the water supply of Virginia City, Nev., in 1872-73. His activities extended to the Hawaiian Islands where he was Consulting Engineer for the Haiku Ditch Company, Island of Maui, and constructed about twenty wrought-iron, riveted, asphaltum-coated pipe lines on that island. He designed the sewer system for Coronado Beach, and was consulted on many other engineering problems.

In 1904, Mr. Schussler was asked by the late President Roosevelt as to his availability to become a member of the Isthmian Canal Commission and, a year later, in 1905, he was appointed, but did not serve, on the Board of Consulting Engineers which was named by the President to consider the question of whether the Panama Canal should be built as a sea-level canal or should be of the lock type.

The last notable structure which was carried to completion under Mr. Schussler's direction was the dam across the Klamath River, California, erected for the California-Oregon Power Company, and generally referred to as the "Copco" Dam. This is a concrete structure of the gravity type, notable for the fact that it closes a narrow subsurface gorge, 120 ft. deep, from which a gravel deposit had to be removed. The dam, in the main, was constructed on the interlocking block system, of quite dry concrete, requiring ramming — a system positive in results and much favored by Mr. Schussler.

On all the work in his charge, he was never satisfied with any that would just pass, that was "good enough". He insisted that it must be "first class", and the results he obtained speak for themselves.

To those who worked with him, and to all with whom he came in contact, he was kind and considerate, and he was successful in commanding a loyalty of subordinates that could only be the result of respect and appreciation of his honesty of purpose and his affectionate and sympathetic nature. He remained vigorous in body and mind to the day of his death.

Mr. Schussler was a good citizen, a thorough believer in American ideals, and enjoyed association with his fellow men. He was very fond of European travel, having made some twenty trips abroad, where he kept up his affiliations with the prominent engineers of England, France, and Italy.

He was married to Miss Louise A. Menges, on March 11th, 1869, and is survived by his widow and three children, Mrs. Martin Preuss, Alice C. Schussler and Dr. Hermann Schussler, Jr.

Mr. Schussler was elected a Member of the American Society of Civil Engineers on February 4th, 1914.

NAOJI SHIRAISHI, M. Am. Soc. C. E.*

DIED FEBRUARY 17TH, 1919.

Naoji Shiraishi was born at Tochi, a village in Kochi Prefecture, Japan, on October 29th, 1857. When he was in his teens, Japan was passing through the crisis preceding the Restoration of the Imperial Rule, and in those days there was more call for the arts of war than for those of peace. He early showed his far-sightedness in applying himself to the study of European languages, in utter disregard of the general cry for the need of warlike training for boys of his age. In 1870 he went to Yokohama and studied English under the Rev. S. R. Brown. In 1875 he entered the Kaisei Gakko, the predecessor of the present Tokyo Imperial University, for the study of Civil Engineering, and was graduated from that institution in July, 1881.

In 1883 he was sent by the Government to the United States to complete his study in that branch of knowledge. Entering Rensselaer Polytechnic Institute, he studied mostly under William H. Burr, M. Am. Soc. C. E. When Professor Burr took service with the Phœnix Bridge Company, Mr. Shiraishi accompanied him and was cordially given the freedom of both office and works to make a special study of bridge construction. He was deeply influenced by the personality and erudition of Professor Burr, and an intimate friendship grew up between the two men. Later, Mr. Shiraishi entered the service of the Pennsylvania Railway Company, to acquaint himself with the practice of railway engineering. Subsequently, he left America for Germany, and, while staying in Berlin, attended the lectures of Professor Winkler, in the Technische Hochschule in that city.

Returning to Japan in 1887, from a tour through the various countries of Europe, Mr. Shiraishi was appointed a Professor in the College of Engineering of Tokyo University. While holding that position, he acted as an adviser to the then organized Kansai Railway Company, in the location and construction of its lines. In those early days of railway construction in Japan, when the lines in operation in the country totaled not more than 1 000 miles, the services of expert engineers were not easily obtainable. The difficult nature of the work on the Kansai Railway having required the exercise of the highest technical knowledge, Mr. Shiraishi was called from his academic chair to give his undivided attention to the task, and, on his resignation of the professorship in 1890, he was made the first President and Chief Engineer of the Company. As Chief Engineer, he gathered around him, as his assistants, many of his former pupils at the University, and carried to a successful issue one of the most difficult railway works in the country. This achievement had far-reaching consequences, in that those young men whom he had trained in the classroom and in

* Memoir prepared by I. Hiroi, M. Am. Soc. C. E.

the field went forth as competent engineers and distinguished themselves in various works of importance with which they were entrusted later.

In 1891 he had conferred on him the degree of Kogaku Hakushi, the title of the highest academic honor in Japan for the profession. In 1898, he resigned his position with the Kansai Railway Company, the construction work of the latter having been completed.

In 1899 Mr. Shiraishi was appointed a member of the Railway Council, the highest advisory board for discussing matters relating to the railway systems in Japan. In the same year, at the request of the Kyushu Railway Company—another company in which he was interested—he again visited Europe and America to make investigations of the methods of shipping coal in those countries. He selected the Brown coal hoist, as the one best fulfilling the requirements of the Company, and, having made a purchase of three machines, each of 5 000 tons capacity, erected them at the terminal yard of the Company.

In 1910 he was made President of the Wakamatsu Harbor Improvement Company, and continued in that position for nine years, during which time he carried out the construction of breakwaters and quay walls, and extensive dredging of the harbor. Under his able guidance, the harbor has become the most important coaling port in Japan, the quantity of coal annually seeking outlet at the port reaching 7 000 000 tons. Along the shore of the harbor stand the Government Steel Works and other large factories, and the busy shipping traffic has transformed the waste flat of former years into an excellent harbor, crowded with sailing ships and steamers.

At about that time, Mr. Shiraishi acted also as Consulting Engineer to the Mitsubishi Company, and designed and constructed breakwaters, quay walls, metallic piers, warehouses of reinforced concrete, dry docks, etc., for that Company at Nagasaki and Kobe. The 7 000-ton floating dock built at the Kobe Shipyard and the use of caisson blocks of reinforced concrete for the breakwaters and quay walls there, were the first engineering feats of the kind in Japan.

In 1907, at the request of the Corean Government, he planned a system of railway lines in the southwestern part of the Peninsula. The present lines between Taiden, Gunzan, and Moppo are substantially the realization of his plans.

From 1911 to 1919 Mr. Shiraishi was Managing Director of the Inawashiro Hydro-Electric Power Company, which has for its work the utilization of the waters of Lake Inawashiro, 140 miles from Tokyo, for the development of electric power. The lake is 44 sq. miles in area and is 1 000 ft. above sea level. An average volume of water of 840 cu. ft. per sec. is now utilized, in two stages, producing electric power aggregating 92 000 h. p., which is transmitted to Tokyo at a pressure of 115 000 volts. The works are now being enlarged by utiliz-

ing the tail-water, so that before long the total output will amount to 130 000 h. p.

Mr. Shiraishi was married in 1882 to Miss Kikuko, a daughter of Mr. Tsuna Takenouchi, a prominent financier. He is survived by his widow and two sons. The elder of these sons follows his father's profession as a civil engineer, and the younger is an electrical engineer.

It is the lot of but few men to be able to accomplish so much in life as Mr. Shiraishi. His practice covered almost all branches of civil engineering, and the works in which he was engaged were of such magnitude as has scarcely been equalled by any in Japan.

Mr. Shiraishi will long be remembered, not only for his achievements as an engineer, but also for his personal qualities. His admirable character made him popular with all who came in contact with him. Although he was not a professed Christian, he was so much inclined to that belief that his interment was made according to its rites.

Mr. Shiraishi was a Member of the Institution of Civil Engineers of Great Britain. In January, 1919, he was elected President of the Japan Society of Civil Engineers. Beside being an engineer of the foremost rank, he was no less a politician, having occupied a seat in the House of Representatives of the Imperial Diet, to which he had been returned three times, and, as a member of the Seiyukai party, was a prominent figure in political circles.

Mr. Shiraishi was elected a Member of the American Society of Civil Engineers on October 4th, 1899.

HARRY GODFRED SIDENIUS, M. Am. Soc. C. E.*

DIED NOVEMBER 7TH, 1918.

Harry Godfred Sidenius was born in New York City on June 21st, 1881, and was educated at the Technical School of Copenhagen, Denmark.

Between 1904 and 1907 he was employed as Assistant and Chief Assistant to William Ingham, Chief Engineer on the design and construction of the water-works system at Port Elizabeth, Cape Colony, South Africa.

In 1907 Mr. Sidenius moved to Canada, and, during 1908-09, was engaged with Messrs. Smith, Kerry and Chace, Engineers on the City of Winnipeg power projects. From 1909 to 1913 he was employed in the Natural Resources Department of the Canadian Pacific Railway Company, chiefly as Resident Engineer of Construction of the Bassano Dam, on the Bow River, Alberta, one of the most noted structures of its type which has ever been built.

During 1914 and 1915 Mr. Sidenius was engaged as Assistant to the City Engineer of Calgary, Alberta, chiefly in connection with the studies and design of that city's water supply. During 1916 and part of 1917 he was attached to the Fourth Field Troop, Canadian Engineers, with rank of Captain, as Instructor at Sarcee Camp, Calgary, Alberta, Military District No. 13, in "Military Engineering and Trench Warfare." For 18 months previous to his death, he was Assistant to the Chief Engineer, Natural Resources Department, Canadian Pacific Railway Company, at Calgary, Alberta.

Mr. Sidenius was married in 1912 at Montreal, Que., Canada, and is survived by his widow and two children aged 4 and 6. His kindly and unassuming nature, his sterling integrity, and his ability as an engineer endeared him to all whose privilege it was to know him.

He was elected to membership in the Engineering Institute of Canada in May, 1915, and always took an active interest in the affairs of the Calgary Branch.

Mr. Sidenius was elected an Associate Member of the American Society of Civil Engineers on January 2d, 1912, and a Member on June 24th, 1914.

* Memoir prepared by A. S. Dawson, M. Am. Soc. C. E.

RAPHAEL CHART SMEAD, M. Am. Soc. C. E.*

DIED NOVEMBER 28TH, 1919.

Raphael Chart Smead was born at Washington, D. C., on October 25th, 1859. His father, the late Capt. J. R. Smead, was a graduate of West Point, a soldier in the Civil War, and was killed in the Battle of Bull Run. His grandfather, the late Capt. R. C. Smead, Corps of Engineers, U. S. Army, who was also an Army officer, was killed in the Mexican War.

After his preliminary education in the public schools, Mr. Smead studied under a private instructor for one year.

In 1878, he was employed as Rodman and Instrumentman making railway surveys on the Union Pacific Railway, and remained on this work until 1880. Between 1880 and 1881, he was engaged as Instrumentman on the Baltimore and Ohio Railroad; between 1881 and 1882, as Assistant and Resident Engineer on construction on the Norfolk and Western Railroad, between 1882 and 1883, as Resident Engineer on the Grafton and Greenbrier Railroad; and between 1883 and 1885, as Assistant and Resident Engineer on the Baltimore and Ohio Short Line Railroad.

In May, 1885, Mr. Smead was appointed United States Assistant Engineer in the office of the Washington Aqueduct, District of Columbia, where he remained until August, 1905. During that time, he was engaged on the work of building the dam at Great Falls and the tunnel between the Georgetown and McMillan Park Reservoirs, and as Superintendent of Maintenance and Operation of the Washington Aqueduct.

In August, 1905, he was transferred to the Dallas Engineer District where he was employed as U. S. Assistant Engineer until October, 1917. From October, 1917, to February, 1919, he served as U. S. District Engineer, at Galveston, Tex., and from that date until November 28th, 1919, as Principal Assistant Engineer of the Galveston District.

In 1918, Mr. Smead was commissioned a Major in the Engineer Officers' Reserve Corps, but was never called to active duty.

He was a man of pleasing personality and social disposition, who made friends easily and was liked and respected by all his associates. He died very suddenly while engaged on his regular official duties and is survived by his wife and one daughter.

Mr. Smead was elected a Member of the American Society of Civil Engineers, on February 1st, 1905.

* Memoir prepared by E. D. Hardy, M. Am. Soc. C. E.

EDWIN FOSTER SMITH, M. Am. Soc. C. E.*

DIED JANUARY 26TH, 1920.

Edwin Foster Smith was born in Catawissa, Pa., on August 18th, 1841. He was graduated from Union College, Schenectady, N. Y., in 1862, with the degree of A. B., and received the degree of C. E. from the same college in 1886.

His father, James Foster Smith, served the Schuylkill Navigation Company and its affiliate, the Philadelphia and Reading Railroad Company, in important positions, from 1843 until his retirement from engineering work in 1885.

Edwin Foster Smith spent his entire life of engineering activity—forty-nine years—in the service of the same two companies, entering that of the Railroad Company as Rodman and Leveler in 1862, and that of the Navigation Company as Assistant Engineer, under his father, in 1865, continuing in their service until his retirement, at the age of seventy, on September 30th, 1911. The activities of father and son, in the service of these two companies, thus covered a period of sixty-eight years.

On March 1st, 1876, Mr. Smith was made Chief Engineer of Canals for the Schuylkill Navigation Company and the Susquehanna and Tidewater Canal Company, and on February 25th, 1885, Superintendent and Engineer of Canals of the Philadelphia and Reading Railroad Company, Lessee.

From 1891 to 1895 he was engaged as Engineer in Charge of Construction of the Reading Terminal and the Terminal Railroad, at Philadelphia, Pa.; and from that time until his retirement in 1911 he acted as Superintendent of the Reading Terminal and Power Houses.

During much of his term of service with the two companies mentioned, Mr. Smith was also engaged in private engineering work, largely in connection with hydraulic operations. This work included the reconstruction, in 1876, of the timber dam, 6 843 ft. long, across the Susquehanna River, at Columbia, Pa.; consulting practice in connection with the water supplies of Reading and Norristown, Pa.; a report on the Castle Wood Dam near Denver, Colo.; the design of hydro-electric power plants near Delta, Pa.; the dam of the Concord Water Power Company on the Merrimac River at Concord, N. H.; and the dam of the Sissiboo Falls Paper Company at Weymouth, Nova Scotia. In 1891, Mr. Smith submitted, for the Philadelphia and Reading Railroad Company, a plan for the utilization of certain of the plants of that Company for the extension of the Philadelphia water supply.

* Memoir prepared by John C. Trautwine, Jr., Assoc. Am. Soc. C. E.

He served as Consulting Engineer and Referee in a number of cases involving testimony on engineering matters in the Pennsylvania and the United States Courts, including the condemnation proceedings of the U. S. Government in taking over the slack-water navigation of the Monongahela River, from Pittsburgh to Geneva, Pa., eighty-nine miles in length.

In 1901, Mr. Smith was engaged as Consulting Engineer to the Board of Engineers of the Aqueduct Commission of New York City, examining the construction of the new Croton Dam and Jerome Park Reservoir.

During the Civil War he served in the Pennsylvania State Militia and in the 26th Regiment, U. S. Emergency Volunteers, and, later, in the Government service of the Philadelphia and Reading Railroad.

He was a member of the Franklin Institute of Pennsylvania, a member and Past-President of The Engineers' Club of Philadelphia, and a member of the University Club of Philadelphia.

It was the writer's good fortune to enjoy friendly and professional intercourse with Mr. Smith, who was a kindly and always courteous gentleman, with a quiet and charming sense of humor.

Mr. Smith was elected a Member of the American Society of Civil Engineers on June 5th, 1895.

FRED CASWELL STANTON, M. Am. Soc. C. E.*

DIED JANUARY 24TH, 1919.

Fred C. Stanton, son of Fred O. and Rebecca Stanton, was born at Vineyard Haven, Mass., on June 7th, 1880. He attended the Vineyard Schools, and was graduated from Marion Academy and, later, from Dartmouth College, taking both the B. A. and C. E. degrees.

During one of his vacations, while attending the Thayer School, Mr. Stanton was employed at Cape May, N. J., on the harbor protection work, under the Engineer Corps, United States Army.

After his graduation, he was employed by the same Department on the improvements of the Brazos River, Texas, under Maj. Jadwin, U. S. A. He was stationed at Houston, Galveston, and at various points along the Brazos River. He was also employed on the Rio Grande River, on the Texas border, and built the ship channel between Houston and Galveston.

When Gen. George W. Goethals, M. Am. Soc. C. E., was put in charge of the construction of the Panama Canal, Mr. Stanton as Civilian Engineer was engaged on concrete construction and dredging in the Canal Zone. Later, he was advanced to the position of First Assistant Engineer of the Atlantic Division of the Panama Canal, under his former chief, Maj. Jadwin, and, later, under Gen. W. L. Sibert, U. S. A., M. Am. Soc. C. E. He designed and constructed the harbor works for the protection of the new harbor at Cristobal, including both the great breakwater at Toro Point and the Eastern Breakwater.

After some eight years of service in the Canal Zone, his health, and also that of Mrs. Stanton, was affected by the tropical climate, and this, with the desire to engage in business for himself, led him to resign from the Canal service in March, 1914.

Mr. Stanton returned to the United States and organized the Stanton-White Dredging Company, which company purchased a number of dredges and engaged in work on reclamation projects in the Mississippi Valley. This work continued until 1918, when labor troubles, occasioned by the draft, considerably restricted the operations of the firm.

On the entrance of this country into the World War, Mr. Stanton was very desirous of enlisting in one of the active branches of the Army, but on the advice of friends who knew his qualifications as an engineer and his familiarity with maritime affairs, he was offered, and accepted, a position with the United States Shipping Board, Emergency Fleet Corporation, as District Plant Engineer of the Southern District, with

* Memoir prepared by J. M. Clack, Assoc M. Am. Soc. C. E., and R. B. Kyle, M. Am. Soc. C. E.

headquarters at Jacksonville, Fla. He was enthusiastically engaged in this work, when stricken with influenza in January, 1919, which developed into pneumonia, and he passed away at the hospital, in Jacksonville, on January 24th, 1919.

Mr. Stanton was married to Elizabeth Stokes, of Jersey Shore, Pa., on October 25th, 1909, who survives him. Mrs. Stanton always accompanied him to all the positions he held from the date of their marriage.

His organization in the Emergency Fleet Corporation and his many friends are left to mourn the loss of a real executive and a true friend.

Mr. Stanton was elected an Associate Member of the American Society of Civil Engineers on April 1st, 1908, and a Member on December 31st, 1913.

HENRY MORTON STONE, M. Am. Soc. C. E.*

DIED DECEMBER 8TH, 1918.

Henry Morton Stone, the eldest son of the late John William and Hannah Ann (Cowpland) Stone, of Glen Loch, Pa., was born in West Nantmeal Township, Chester County, Pa., on April 28th, 1858.

He was educated at Treemount Seminary, Norristown, Pa., where he studied engineering under the late Dr. John W. Loch. His earliest engineering experience was with railroads in the East, but the greater portion of his life was spent in the service of Western roads, or in the employ of Chicago interests.

Mr. Stone's first work was with the Pennsylvania Railroad, Eastern Lines, where he was engaged in the location and construction of the road from Whitings to Bay Head Junction, N. J., and of the "Cut Off" at Lancaster, Pa.

He resigned from the Pennsylvania Railroad to accept a position with the Denver and Rio Grande Railroad, having had charge of the construction of a section of that road in the Rocky Mountains near Dillon, Colo. With the temporary abandonment of this work, he accepted a position with the St. Louis, Iron Mountain and Southern Railroad, and, later, returning to his native State, was employed by a corporation known as the Delaware River, Phoenixville, and Lancaster Railroad to locate a railroad through the northern part of Lancaster and Chester Counties. He resigned to accept a position with the Lehigh Valley Railroad Company at Sayre, Pa. While with the Lehigh Valley, he was engaged in making surveys for the entrance of that railroad into Buffalo.

In 1883, Mr. Stone again went West, and accepted a position with the Chicago and Northwestern Railroad, with which he remained for more than five years, his principal work being the construction of new lines in the Northern Peninsula of Michigan.

After leaving the Northwestern, he was for a time Engineer of the Cairo Land and Construction Company, and in that capacity had charge of the construction and maintenance of the dikes at Cairo, Ill. Mr. Stone resigned this position to enter the service of the Chicago, Milwaukee and St. Paul Railroad, where he had charge of double-tracking a considerable section of that road near Marion, Iowa. His next position was with the municipality of Wilmette, Ill.

In 1896, Mr. Stone was sent by a Chicago syndicate of capitalists to Cape Breton, Nova Scotia, to locate and build a railroad (with docks and terminal facilities) from the Western Coast to the coal fields. In 1900, he became Location Engineer for the Algoma Central Railway,

* Memoir prepared by J. W. Stone, Esq.

in which capacity he located a considerable portion of the present line of that road. Later, he was appointed Bridge Engineer of the same corporation.

On January 1st, 1903, he entered the service of the Chicago, Rock Island and Pacific Railroad, with which corporation he remained until his death, at different times holding the positions of Assistant Engineer at Lincoln, Nebr., Division Engineer at Fairbury, Nebr., and Little Rock, Ark., Location Engineer in charge of location and construction in Texas and Louisiana, District Engineer of the Northern District at Cedar Rapids, Iowa, and of the Southwestern District at Topeka, Kans., and Chief Engineer of the Chicago, Rock Island and Gulf at Fort Worth, Tex. With the abolishment of that position he was for a time with the Valuation Department, and, at the time of his death, was Engineer of Construction in charge of extensive double-track work authorized by the Federal Administration, at Trenton, Mo.

Prior to going to Trenton, Mo., Mr. Stone had been loaned by the Rock Island Railroad Company to the Union Pacific Railroad to take charge of the field work of the reconstruction of the Grand Island Bridge crossing the Missouri River at St. Joseph, Mo.

He was married in Chicago, on September 11th, 1889, to Miss Henrietta Reigart, daughter of Adam W. and Mary Bender Reigart, formerly of Lancaster County, Pa.

He is survived by his widow, residing at Kansas City, Mo., and one son, Morton Reigart Stone, Superintendent of the Idaho Fruit Products Company at Meridian, Idaho.

Mr. Stone was elected a Member of the American Society of Civil Engineers on April 3d, 1907.

ARNOLD HENRY SUTERMEISTER, M. Am. Soc. C. E.*

DIED JUNE 30TH, 1918.

Arnold Henry Sutermeister was born at Fort Wayne, Ind., on November 16th, 1869. His father, the late Arnold Sutermeister, who was born in Switzerland, was a prominent contractor in the West, having been engaged in business in Fort Wayne, Ind., and Kansas City, Mo. He was a Captain in the Civil War, and commanded the Eleventh Indiana Battery, which command he himself raised at Fort Wayne. This battery shared, to a great extent, in the hottest fighting of the War. Capt. Sutermeister was also with Sherman in his famous march to the sea. Mr. Sutermeister was always very proud of his father's military record.

Mr. Sutermeister spent his early boyhood and received his schooling at Fort Wayne, and, during his early 'teens, went to Kansas City, where he attended High School. J. A. L. Waddell, M. Am. Soc. C. E., a personal friend of his father, was instrumental in sending the young man to Rensselaer Polytechnic Institute. He took the examinations for the Institute in Mr. Waddell's Kansas City office.

He took the civil engineering course at Rensselaer, was graduated in June, 1892, and then entered the service of the United States Geodetic Survey, being engaged as Transitman on the survey of the Hudson River until the fall of that year, when he accepted a position as Assistant Division Engineer on the Mohawk Division of the New York Central and Hudson River Railroad, at Albany, N. Y. He was quickly promoted to Division Engineer of the same Division, and retained that position until July, 1894, when he entered the employ of the Troy Union Railroad, at Troy, N. Y., first as Roadmaster and then as Superintendent and Engineer, in which capacity he had charge of the design and erection of railroad masonry and bridges.

In July, 1898, Mr. Sutermeister was appointed Engineer in Charge of the Elimination of Grade Crossings for the Board of Railroad Commissioners of New York State, later known as the Public Service Commission, Second District. This position he held until his death, which occurred on June 30th, 1918, at Albany, as the result of an unusual accident in which he sustained a fracture of the skull, due to a blow received when a demountable rim flew from the wheel of his automobile while he was adjusting it. His long service of 20 years as Engineer of Grade Crossings of the Public Service Commission, speaks for the quality of his professional work.

Some of the structures of the grade crossing work, with the design and execution of which he was directly connected, were: The Chenango

*Memoir prepared by J. W. Pfau, M. Am. Soc. C. E.

Street Viaduct, at Binghamton, over the Erie and Delaware, Lackawanna and Western Railroads; the elevation of the New York Central tracks through Schenectady and through Yonkers; the elimination of the grade crossing at North Pearl and Von Woert Streets on the main line of the New York Central Railroad, in Albany, and also many other grade crossing eliminations throughout the State, from three hundred to four hundred works of this kind having been built during the period in which Mr. Sutermeister served the Commission.

In 1895 Mr. Sutermeister was married to Miss Caroline M. Kreischer, of Albany, who, together with two sons, Arnold, age 19, and Karl, aged 16, survives him. He was a man of pleasing personality and sterling character, and was possessed of particularly sound judgment. His most pronounced characteristic was his sense of fairness. He not only had the desire but also the ability and determination to be fair, a particularly desirable trait for one in the position he held, where engineering decisions had to be made to meet, as nearly as possible, the views and desires of all the various interested parties, namely, adjoining property owners, municipalities, and railroad companies. Mr. Sutermeister was of a modest and retiring disposition, and was a firm believer in the simple life.

He was a member of the University Club of Albany, Sons of Veterans, and the Rensselaer Society of Engineers, and had served as President of the Eastern Division of the Rensselaer Alumni Association.

Mr. Sutermeister was elected a Member of the American Society of Civil Engineers on June 3d, 1902.

CARL UHLIG, M. Am. Soc. C. E.*

DIED MAY 4TH, 1919.

Carl Uhlig was born in Chemnitz, Saxony, on December 31st, 1846. He was educated in Saxon schools and was graduated from the Polytechnic School in Dresden in 1867.

He came to the United States in 1868 and shortly afterward entered the service of the United States Coast and Geodetic Survey as Aid, having been engaged in work at various points on the coast of California, principally at San Pedro and Crescent City.

In 1876, Mr. Uhlig entered the employ of the Board of State Harbor Commissioners in San Francisco as Chief Draftsman, being later appointed Assistant Engineer, and remained in that position continuously for 43 years, until his death. During that time he was connected with the design of the numerous bulkhead wharves, piers, ferry slips, sea walls and other water-front structures built by the Board, and accumulated a fund of information bearing on the hydrographic and topographic conditions of the San Francisco frontage that was particularly valuable and made of him an authority on this subject, consulted by all who contemplated any engineering work in that vicinity.

Mr. Uhlig was a man of high character, scrupulous integrity, and amiable personal qualities. He had a wide circle of friends in all walks of life and was regarded with feelings of esteem and affection by all who enjoyed the privilege of his friendship. The best tribute to his ability as an engineer is the fact of his having been retained in his position by his employers, the Board of State Harbor Commissioners, during the political vicissitudes of over 40 years; though the personnel of the Board was changed repeatedly, his thorough knowledge of conditions was considered invaluable and no attempt was made to replace him.

Mr. Uhlig never married, and is survived by two sisters. He had been in failing health for some years, and his death from heart disease on May 4th, 1919, was not entirely unexpected.

Mr. Uhlig was elected a Member of the American Society of Civil Engineers on October 7th, 1903.

* Memoir prepared by the following Committee of the San Francisco Section of the American Society of Civil Engineers: Frank G. White, Howard C. Holmes, and Jerome Newman, Members, Am. Soc. C. E.

GEORGE WESTON, M. Am. Soc. C. E.*

DIED JANUARY 7TH, 1920.

George Weston was born in Kalamazoo, Mich., on January 30th, 1861.

He began his professional career in 1880 when he entered the Engineering Department of the Missouri, Kansas and Texas Railway as Rodman, serving in this position until 1883.

From 1885 to 1887, he was employed as Rodman, Instrumentman, and Assistant Engineer in charge of construction with the Gulf, Colorado and Santa Fé Railroad.

In 1887, Mr. Weston established relations with the late Charles T. Yerkes, of Chicago, Ill., and was engaged until 1896, as Engineer in charge of the construction of a number of miles of cable and electric street railway track in that city.

From 1896 to 1901, he served as Manager of the Construction Department of Naugle, Holcomb and Company of Chicago, Ill., having been engaged as follows: In 1896 and 1897, as Chief Engineer on the construction of the "Suburban" Railroad, Chicago; in 1898, he made examinations and reports on steam railroad and electric properties for the firm; and from 1898 to 1901 he had full charge as General Manager and Chief Engineer of the construction of 66 miles of the Tennessee Central Railroad.

From January, 1901, to 1907, Mr. Weston was associated with his brother, Charles V. Weston, M. Am. Soc. C. E., and also with Bion J. Arnold, M. Am. Soc. C. E., and the Arnold Company, of Chicago, in practice as a Consulting Engineer on valuation work and in making reports pertinent to electric traction operations.

When the Board of Supervising Engineers of the Chicago Traction Company was organized in 1907, Mr. Weston was appointed Assistant Chief Engineer and, at a later date, became the representative of the city on that Board and Engineer for the Board which latter position he retained until January, 1919. At the time of his death he was President of Weston and Company, Consulting Engineers, of Philadelphia, Pa., having been retained as Consulting Engineer for the Philadelphia Rapid Transit Company. He was also conducting work in connection with valuation matters for the Public Service Railway of New Jersey.

Mr. Weston died suddenly in Philadelphia, Pa., on January 7th, 1920, from acute indigestion, and is survived by his widow and two brothers, Charles V. Weston, M. Am. Soc. C. E., and Joseph Weston.

He was one of the best known experts on electric street railway affairs in the United States, and his work in connection with the construction and electrification of railroads and street railroads was exten-

* Memoir prepared by Horace L. Howell, Esq., New York City.

sive throughout the Middle West. He had also been active in questions of valuation and industrial relations and had written many papers in reference to these subjects.

Mr. Weston was admired by his associates for his qualities of capability, loyalty, fairness, and the intense energy which characterized his work.

He was a member of the Western Society of Engineers, the American Electric Railway Association, for which, in connection with his work on its Committee on Valuation, he had just completed a report outlining procedure and methods of deriving and attaining fair value for electric railway properties, the Engineers' Clubs of New York City and Chicago, and the Chicago Athletic Club. He was also active in Masonic circles.

Mr. Weston was elected a Member of the American Society of Civil Engineers on June 5th, 1907.

RUFUS MASON WHITTET, M. Am. Soc. C. E.*

DIED DECEMBER 10TH, 1918.

Rufus Mason Whittet, son of Alexander and Isabella (Proudfoot) Whittet, was born on October 17th, 1878, in Lowell, Mass. He came of Scotch ancestry, being a lineal descendant of James Whittet, of Kintillo, Scotland.

He was educated in the Lowell public schools, having been graduated from the Moody Grammar School in 1893 and from the Lowell High School in 1897, at the age of nineteen. Deeming it wise to continue his academic studies further, he returned the following year to the Lowell High School, taking the Post Graduate Course.

Mr. Whittet then passed the entrance examinations for both Harvard College and the Massachusetts Institute of Technology. Deciding in favor of Technology, he entered that institution in 1898 and was graduated in June, 1902, with the degree of Bachelor of Science in the Department of Sanitary Engineering, presenting as his thesis: "A Study of the Stream Flow Records of the United States Geological Survey."

After being graduated from the Massachusetts Institute of Technology, Mr. Whittet joined the Engineering Staff of the State Board of Health, and in the wide field of work covered by that Department he found employment congenial to his tastes. Taking a deep interest in its work, he soon became a most valued member of its staff, and was the Principal Assistant Engineer of the Department at the time of his death.

He was a civil engineer who believed in the elevation and dignity of his profession, and he acted on this belief with a fine enthusiasm. His principal characteristics, clear thinking and sound judgment, were combined with great executive ability, and his early death ended a career begun with great promise.

Mr. Whittet was a member of the Boston Society of Civil Engineers, the New England Water Works Association, and prominent in the Masonic Fraternity.

He was married in September, 1916, to Effie Osgood Byron, of Jamaica Plain, Mass., who, with a daughter, Helen Isabella, born on January 16th, 1918, survives him.

In appreciation of his service to the State, the State Department of Health adopted the following tribute to his memory:

"Rufus Mason Whittet, C. E., Principal Assistant Engineer of this Department, died on December 10th, 1918, a victim of the prevailing influenza epidemic.

* Memoir prepared by X. H. Goodnough, M. Am. Soc. C. E.

Mr. Whittet joined the Engineering Staff of the State Board of Health upon his graduation from the Massachusetts Institute of Technology in 1902, and has been the Principal Assistant Engineer of the Department since 1908.

His energy, thoroughness, clear thinking and sound judgment were of invaluable assistance in the studies of water supply and drainage and the great variety of kindred problems embraced in the work of the Department, while his quiet manner, his fairness, and his kindness made work with him a pleasure. These qualities, with a high sense of honor and loyalty to his associates, made him respected by all and loved by a wide circle of friends."

Mr. Whittet was elected an Associate Member of the American Society of Civil Engineers on May 2d, 1911, and a Member on November 4th, 1914.

ELLIOTT HINCKLEY WILSON, M. Am. Soc. C. E.*

DIED NOVEMBER 27TH, 1918.

Elliott Hinckley Wilson was born in New Orleans, La., on March 25th, 1851. He entered Washington University, where he made a remarkable record, ranking high in every class, and was graduated in 1871, as a Civil Engineer.

In 1870, Mr. Wilson served as Rodman on the St. Louis and South Eastern Railway, and during the next two years as Rodman, Topographer, and Leveler on the Northern Pacific Railway in Montana. In 1873, he was Assistant Engineer on the Cairo and Vincennes Railway, and, in 1874 and 1875, served in the same capacity on the location, construction, and maintenance of the St. Louis, Kansas City and Northern Railway.

During the next two years Mr. Wilson was Assistant Engineer on the Ohio and Mississippi Railway, and entered the service of the Mississippi River Commission in 1878 as Assistant Engineer at St. Joseph, Mo. He remained with this Commission until 1882, having charge of boring operations, under Maj. Suter, a work undertaken to determine the extent and character of the alluvial deposits of the Mississippi and Missouri Rivers. He also had charge of certain river improvements at Atchison, under Maj. Suter.

In 1882, Mr. Wilson accepted the position of Assistant Engineer on the Missouri Pacific Railway, taking charge of the location of the line between Atchison, Kans., and Omaha, Nebr. After that, he was in charge of location and construction for the Union Pacific Railway in Montana, Nebraska, and Idaho, until September, 1884.

At the latter date he formed a partnership with Mr. John Gillie, under the firm name of Wilson and Gillie and, until 1898, conducted a general civil and mining engineering practice at Butte, Mont. In 1898, Mr. Gillie entered the employ of the Anaconda Company, and a little later Mr. Wilson became affiliated with the Heinze interests, remaining with that organization until 1906. For three months in 1889 he acted as General Manager of the Bi-Metallic Mining Company.

Mr. Wilson was a United States Deputy Mineral Surveyor for Montana and Idaho, and for the last few years had devoted himself to private work as an examiner of mining properties for various interests.

He had served a term in the Montana Legislature, was elected a Member of the American Institute of Mining Engineers in 1887, and was one of the Charter Members of the Montana Society of Engineers, having been elected to the Presidency of that Society in 1891. He was

* Memoir prepared from information furnished by Eugene Carroll, M. Am. Soc. C. E., and on file at the Headquarters of the Society.

one of the pioneer members of the Silver Bow Club of Butte, Mont., and made his home there.

Mr. Wilson suffered from a malignant affliction of the throat, and was with difficulty persuaded by his friends to seek relief in the hospital at Warm Springs. He died there on November 27th, 1918. He is survived by three sisters, Mrs. M. S. Smith, of Fort Collins, Colo., Mrs. W. Bradford, of Waverly, Ill., and Miss Josie Wilson, of Granville, Ill.

Mr. Wilson was elected a Member of the American Society of Civil Engineers on February 1st, 1888.

IRVING SPARROW WOOD, M. Am. Soc. C. E.*

DIED OCTOBER 20TH, 1919.

Irving Sparrow Wood, born in Providence, R. I., on November 27th, 1857, was the son of Charles P. and Sarah S. (Robinson) Wood. He was of New England parentage. His education was obtained from the public schools of his native city, supplemented by a course in Mowry and Goff's English and Classical School, a local institution, from which he was graduated in June, 1877.

Mr. Wood promptly took up the line of work which he was destined to follow during his life, entering the office of the City Engineer of Providence and working there in various capacities until the spring of 1881, when he was assigned to the Water Department, then in charge of the late Edmund B. Weston, M. Am. Soc. C. E. He soon became First Assistant, acting as such until May 1st, 1899, when he was appointed to the vacancy caused by the resignation of Mr. Weston. This position he held until his death on October 20th, 1919, which occurred in the house in which he was born.

During the twenty years of his administration, the population supplied by the Providence Water-Works increased from about 180 000 to nearly 300 000, and the annual consumption of water rose from about 3 500 000 000 gal. to nearly 8 000 000 000 gal. This expansion required a corresponding increase of the distributing pipes year by year and the installation of more ample and efficient pumping machinery. An extensive and highly successful filtration system was also introduced.

Mr. Wood was affiliated with the Boston Society of Civil Engineers, the New England Water Works Association, and the Providence Engineering Society.

He was married on October 14th, 1903, to Miss Margaret E. Read, who survives him.

Modest and unassuming in demeanor, Mr. Wood was diligent and conscientious in the performance of his official duties, courteous and fair with his subordinates, agreeable as an associate, and faithful and considerate as a friend.

Mr. Wood was elected a Junior of the American Society of Engineers on March 5th, 1890, an Associate Member on March 7th, 1900, and a Member on March 6th, 1906.

* Memoir prepared by Herbert E. Sherman, M. Am. Soc. C. E.

WILLIS BENTON WRIGHT, M. Am. Soc. C. E.*

DIED NOVEMBER 16TH, 1919.

Willis Benton Wright was born in Pittsfield, Mass., on February 25th, 1860. He was a son of Samuel Augustus Wright and Ann Maria (Butler) Wright. His father was the son of Samuel C. Wright and Olive (Benton) Wright, and traced his descent to James Wright of Milford and Durham, Mass. (1698). His mother, Ann Maria (Butler) Wright, born in Connecticut, was the daughter of Sylvester and Anna Butler, whose family traced its descent to Richard Butler, a deacon in the church of the Rev. Thomas Hooker. This is the church the members of which came from Boston and settled Hartford, Conn., in 1636.

Mr. Wright was prepared for college at the Middletown, Conn., High School and took the Civil Engineering Course at Sheffield Scientific School, Yale University, where he was a member of Phi Gamma Delta and received a Senior appointment.

After his graduation from Sheffield, Mr. Wright entered the service of Commander Garringe, U. S. N., the Consulting Engineer of Obelisk fame. In 1886, he was engaged on construction work with the Minneapolis, St. Paul and Sault Sainte Marie Railroad, and, later, was employed on the same kind of work in the Cascade Mountains for the Oregon Pacific Railroad, and, in Lower California, Mexico, for the Ferrocarril San Quintin y Yuma.

After two years more in the service of the Minneapolis, St. Paul and Sault Sainte Marie Railroad, and a year's travel, he was appointed, in 1895, Division Engineer of the Drainage Department of the Sewerage and Water Board of the City of New Orleans, La., which position he held at the time of his death on November 16th, 1919.

He was married on May 18th, 1896, in New Orleans, La., to Miss Juliette Pulver, daughter of David Barker Pulver, of that city, by whom he is survived. They had no children.

Mr. Wright had many business and professional qualities. Those who knew him always retained a high regard for his clear-sighted analysis of conditions, his high standard of fair dealing, his integrity, and his tactful treatment of all questions submitted to him. He was an engineer of unquestioned ability, active, energetic, and had endeared himself to all who knew him.

Mr. Wright was elected a Member of the American Society of Civil Engineers on November 3d, 1897. He was also a Charter Member and a Past-President of the Louisiana Engineering Society.

* Memoir prepared by Alfred F. Theard, M. Am. Soc. C. E.

EDGAR HAROLD ANNEAR, Assoc. M. Am. Soc. C. E.*

DIED AUGUST 28TH, 1918.

Edgar Harold Annear was born at Ceres, Cal., on December 30th, 1881. He received his early education in the schools of Ceres and Modesto, and pursued a course in civil engineering at the University of California for two years. He then received an appointment to the West Point Military Academy, but was compelled to give it up at the end of a year because of the prolonged illness of his father.

On returning to California, Mr. Annear was appointed a Deputy United States Land Surveyor, made a survey of Government lands in Monterey County, and, later, engaged in the practice of surveying and irrigation engineering in Stanislaus County, California.

In 1906, he was elected County Surveyor of Stanislaus County, and was re-elected without opposition in 1910 and again in 1914.

In January, 1918, Mr. Annear resigned his office to take a commission in the Engineer Reserve Corps, U. S. A., and, after three months' training at American University, Washington, D. C., was sent to France in command of Co. B, 43d Regiment of Engineers, U. S. A. He had been promoted to the rank of Major, and had returned to the United States to take back combatant troops, when he was taken suddenly ill, soon after landing at Hoboken, N. J., and died there on August 28th, 1918.

During his term of office as County Surveyor, Maj. Annear was in charge of the planning and construction of a great number of roads and bridges, which were required by the rapid development of the county. He realized the ultimate desirability of permanent and esthetic structures, and the bridges of Stanislaus County are lasting monuments to his genius and constructive ability.

In the latter part of 1916, the people of Stanislaus County voted bonds for the construction of 126 miles of concrete highways. The successful promotion of this project was due, in a large degree, to the untiring effort with which Maj. Annear devoted himself to the education of the people to the necessity and ultimate economy of permanent roads, and, after the bonds were voted, he was placed in direct charge of their planning and construction. With an energy which was characteristic of him, he perfected a highway organization, completed surveys and plans, and succeeded in getting construction under way with such speed that, notwithstanding the ever increasing shortage of labor and material, he was able to see the completion of all but about 18 miles of the system before his resignation in January, 1918.

* Memoir prepared by D. M. McPhetres, Esq.

The highways which were built under his direction are conceded to be among the best in the United States.

Maj. Annear was an engineer of the highest integrity and ability. He kept constantly in touch with his work, was possessed of a strong grasp of detail, and the high class of workmanship which is evident in all his work is due largely to his own personal supervision. Under the most trying circumstances, he was always cheerful, was ever ready to overlook the errors of others, and his kindly smile and cheerful greeting made him beloved by his associates and all who knew him.

In July, 1909, he was married to Miss Margaret L. McFarland, who, with a daughter, survives him.

Maj. Annear was elected an Associate Member of the American Society of Civil Engineers on March 5th, 1912.

BERNT BERGER, Assoc. M. Am. Soc. C. E.*

DIED JANUARY 16TH, 1919.

Bernt Berger was born in Drammen, Norway, on July 12th, 1866. He was graduated from the High School there in 1881, and from the Mechanical Engineering Branch of the Technical Institute of Trondhjem, Norway, in 1885.

After one year's employment in the City Engineer's Office in Drammen, Mr. Berger came to New York City, arriving on September 14th, 1886, and almost immediately entered the employment of the late Theodore Cooper, M. Am. Soc. C. E., Consulting Bridge Engineer, with whom he remained until the latter retired from business in 1908, when Mr. Berger succeeded to his very important consulting practice, in addition to what he had individually developed along similar lines.

Mr. Berger's great accuracy and careful methods of investigation and sound treatment of technical subjects won for him the complete confidence of Mr. Cooper and his clients, and he developed a great capacity for handling successfully difficult structural problems and had responsible charge of many reports, investigations, and designs. He specialized largely in important and long-span steel bridges, general steel construction, masonry and concrete arch spans, reinforced concrete construction, and substructure work.

Among the important structures with which Mr. Berger was connected may be mentioned the Quebec Bridge, the New York Public Library Building, the New York City Elevated Railroad structures, and important bridges for many railroad companies, including some in South America and in Japan. He also specialized in examinations and recommendations for the safety of existing structures and for difficult repair and reconstruction work that was of great value to the engineers, contractors, and architects who were his clients. He was associated with much of the recent New York City subway construction, having been retained to supervise the steelwork on several important sections.

Few of his clients failed to re-engage him whenever they had subsequent work in his field. He was employed frequently by the New York Edison Company and the Edison Electric Illuminating Company, of Brooklyn, The Dayton Light and Power Company, the Utica Gas and Electric Company, the Underpinning and Foundation Company, The U. S. Realty and Improvement Company, The Cranford Company, of Brooklyn, Holbrook, Cabot and Rollins, The Pennsylvania Shipbuilding Company, The New York Tunnel Company, and many other companies and individuals were included among his clients.

* Memoir prepared by Frank W. Skinner, M. Am. Soc. C. E.

Mr. Berger was a Past-President of the Brooklyn Engineers' Club, a member of the Engineers' Club of New York, the American Society for Testing Materials, and of the American Concrete Institute. He was also the Permanent Chairman of the Trondhjem Technical Club and a member of the Crescent Athletic Club, of Brooklyn, and, for many years, one of the Board of Managers and Treasurer of the Norwegian Lutheran Deaconesses Home and Hospital, a Trustee of the Norwegian Sailors' Church, Director of the Norwegian Society, and Secretary of the Hospital Saturday and Sunday Association, all of Brooklyn, N. Y.

Mr. Berger was fond of outdoor life and sports, including golf, sailing, bicycling, and skeeing. Although of a studious disposition, with cultivated literary taste, he found time for much social relaxation with a large circle of warm friends who claimed all his leisure moments. He was especially devoted to the interests of all his fellow engineers and never failed to lend a kindly hand and to have an encouraging word for the younger members of the Profession, many of whom he established in positions among his numerous friends and clients. His purse was always open to the necessities of struggling young engineers or students, and he befriended many of them, especially those who had arrived from abroad with only a few friends and no experience in this country. Mr. Berger lived in Brooklyn for twenty-five years; he was never married, and is survived by one brother in New York City and two brothers in Norway.

By his death on January 16th, 1919, the Society has been deprived of an able, vigorous member, always ready to devote his utmost efforts and zeal for its benefit; the Profession of Civil Engineering has lost a scholar, designer, and constructor; his clients have been deprived of notable skill and practical ability and unusually reliable services that were always rendered with the utmost care and thoroughness on every occasion; while his numerous friends can never forget the genial comradeship and hearty affection that endeared him beyond the ordinary to all with whom he came in close and sympathetic touch.

Mr. Berger was elected an Associate Member of the American Society of Civil Engineers on April 5th, 1893.

WILLIAM BLAIR BOVYER, Assoc. M. Am. Soc. C. E.*

DIED JULY 20TH, 1918.

William Blair Bovyer, the son of Edward Bovyer and Anna (Kearse) Bovyer, was born in San Francisco, Cal., on March 16th, 1887. He received his elementary education in the public schools of San Francisco and attended the Mission High School of that city, from which he was graduated in 1905. He then entered the University of California with the intention of studying law, but soon found, however, that engineering had a stronger appeal for him. He gave up the study of law and began a course in Civil Engineering from which he was graduated in 1910 with the degree of B. S.

For the first two years following his graduation, Mr. Bovyer worked, successively, for the Pacific Rolling Mill Company, Dyer Brothers Iron Works, the United Railroads of San Francisco, Selby Smelting Company, and Maurice C. Couchet, M. Am. Soc. C. E., Consulting Engineer.

In 1912, he became connected with the City Engineer's Office of San Francisco, where he attained the grade of Assistant Engineer. He worked on most of the city's important engineering works of that period and made many of the drawings and designs of the tunnels, sewer systems, water-works, and other structures constructed by the city.

In 1917, Mr. Bovyer was granted a leave of absence from the City Engineer's office and became connected with the work of the Board of State Harbor Commissioners of San Francisco, where he was employed until his death. During this time he was engaged in the design of all classes of water-front structures such as piers, wharves, buildings, etc.

Mr. Bovyer was a man who always put his best efforts into his work, and the record which he made proves that he made no mistake in his choice of a profession. He was a man of pleasing personality and in all his personal and professional relations his outstanding characteristics were kindness and complete sincerity and frankness. His joyous outlook on life and its many problems always acted as an inspiration and a tonic to all who came in contact with him. His genial nature will be long remembered by his friends.

In August, 1915, Mr. Bovyer was married to Miss Cora Niedor, who, with two daughters, Ruth, age four, and Patricia, age one, survives him.

Mr. Bovyer was elected a Junior of the American Society of Civil Engineers on October 1st, 1913, and an Associate Member on September 12th, 1916.

* Memoir prepared by the following Committee of the San Francisco Section of the American Society of Civil Engineers: Frank G. White, M. Am. Soc. C. E., and Leon H. Nishkian, Assoc. M. Am. Soc. C. E.

CHARLES EDWIN BRIGHT, Assoc. M. Am. Soc. C. E.*

DIED APRIL 3D, 1919.

Charles Edwin Bright was born in Sumner County, Tennessee, on December 27th, 1866. He was the son of Dr. Charles T. and Mary Branham Bright.

After attendance at the public schools of Sumner County, Mr. Bright entered Vanderbilt University at Nashville, Tenn., to take up civil engineering, but, in 1887, he had to give up college, after having completed three years of the four-year course.

From June, 1887, to February, 1888, Mr. Bright was engaged as Rodman in the City Engineer Department of Nashville, Tenn., and from February to November, 1888, as Transitman, Leveler, and Resident Engineer on the location and construction of dummy railways and general city surveying.

From January to May, 1889, he was employed on the Florence Northern Railway as Transitman, Leveler, and Assistant Engineer on location and construction in Alabama and Tennessee, and after making a survey for a highway bridge across Duck River, at Columbia, Tenn., in May, 1889, he served as Leveler (June, 1889) on the Louisville and Nashville Railway on the location of 10 miles of double track. In July and August of that year, Mr. Bright was again employed with the City Engineer Department of Nashville as Inspector of granite block pavement for the city. In September, 1889, he entered the employ of the East Tennessee Land Company and had charge of a party making a topographical survey for, and staking out, the Town of Harriman, Tenn., as well as the preliminary surveys and location for the Harriman and Brushy Mountain Railway, on which he also served as Resident Engineer on construction.

From December, 1891, to October, 1895, Mr. Bright was with the United States Engineer Department, Nashville District, on the improvement of the Cumberland River, making location surveys for Locks Nos. 2, 3, and 4. He also acted as Inspector in local charge of the construction of Lock No. 3.

From February to July, 1896, he was engaged as Superintendent for the contractors on the construction of a masonry wall enclosing the Tennessee State Penitentiary and also superintended the construction of a 4-mile extension of the Nashville, Chattanooga, and St. Louis Railway, for the Duck River Phosphate Company.

In July, 1896, he again entered the service of the U. S. Engineer Department, serving until December of that year as Overseer of the Nashville District; from January, 1897, to June, 1898, as Draftsman and Photographer in the office at Nashville; and from June, 1898, to

* Memoir prepared by B. M. Taylor, Asst. Valuation Engr., Louisville and Nashville Railroad, Louisville, Ky.

March, 1900, in local charge of the construction of Lock No. 6 on the Cumberland River. In May, 1900, Mr. Bright was transferred to the Mobile District and put in local charge of the construction of Lock No. 5 on the Warrior River, Alabama, remaining on this work until August, 1901.

At this time, he concluded to exploit his engineering talent in another field, and, for a number of years, was engaged in railroad location and construction on the Tennessee Central Railroad, the Louisville and Nashville Railroad, the Tidewater Railway, and the Nashville, Chattanooga, and St. Louis Railway. On the Tennessee Central Railroad, he was employed as Resident Engineer on construction and Assistant Engineer on maintenance of way. On the Louisville and Nashville Railroad, he was Resident Engineer at Dossett, Tenn., for 2 years, constructing several miles of road, including the Dossett Tunnel. He was then employed for about 14 months on the Tidewater Railway, part of the time on location surveys and part as Resident Engineer on construction. His last railroad work was on various surveys for the Nashville, Chattanooga, and St. Louis Railway, covering about two years prior to April, 1908.

The service of the Government again attracted Mr. Bright, and, in April, 1908, he took charge in the field of the completion of Colbert Shoals Canal and Lock on the Tennessee River at Riverton, Ala., remaining there about five years. On this project he had charge of extensive concrete river wall construction, the grading of the canal trunk, the erection of the massive lock-gates and their maneuvering gear, and the construction of steamboats, barges, and dredges after the canal was opened to traffic.

Malaria contracted at Riverton so affected his health, that he had to give up river work. He then removed to Nashville, Tenn., where, from August, 1913, to August, 1914, under the direction of the City Engineer, he rebuilt that portion of the City Water Reservoir, which shortly before had failed destroying considerable property in its vicinity.

In August, 1914, Mr. Bright became a member of the Engineering Staff of the Division of Valuation, Interstate Commerce Commission, serving as Assistant Field Engineer until June, 1917, and as Field Engineer from that date until his death, which occurred at his home in Nashville, Tenn., on April 3d, 1919.

Mr. Bright was married on May 8th, 1898, to Miss Laura Doxey, of Hendersonville, Tenn.

Throughout his career, he was always loyal to his profession, conscientious and competent in the performance of his duties, and, in his death, the Engineering Profession lost one of its best men.

Mr. Bright was elected an Associate Member of the American Society of Civil Engineers on December 3d, 1902. He had also been a member of the Engineering Association of the South since 1890.

ROBERT EDWARD DAKIN, Assoc. M. Am. Soc. C. E.*

DIED DECEMBER 15TH, 1918.

Robert Edward Dakin was born at Gaylordsville, Conn., on July 2d, 1888. He was graduated from the New Milford High School in 1906, and three years later received the degree of Bachelor of Science (Civil Engineer) from the Sheffield Scientific School of Yale University. In the fall of 1909, following his graduation from Yale, Mr. Dakin entered the service of the New York, New Haven, and Hartford Railroad, in charge of electric railway construction.

Mr. Charles S. Mellen, then President of the New Haven Railroad, in an endeavor to carry out his great plan of a unified transportation system for New England, had acquired for feeders to the steam and water lines an extensive system of trolleys, and, until April, 1917, Mr. Dakin was engaged in the reconstruction of many of these properties, the construction of extensions and connecting links, and, in the latter half of the period, in the preparation of maps, land records, mileage and tax reports, appraisals, and other forms of data, for submission to the various commissions having jurisdiction or interest in various features of the property.

In detail may be mentioned surveys and estimates for the construction of about 20 miles of new trolley line and for the relocation of several smaller sections; the surveys and estimates for an 8-mile, wood pole, transmission line and for an 11-mile, steel tower line, including the construction of the former; the construction of car-houses at Derby and New Haven; of freight-houses at Ansonia, Naugatuck, New Haven, and Waterbury; the enlargement of the Bridgeport steam station; the improvements and additions to the Bulls Bridge hydro-electric plant, the latter work, although not of great magnitude, called for a high degree of ability and ingenuity, as the new penstock and stand-pipe with the concrete pier in the tail-race, and the new head and forebay gates, had to be installed with practically no interference with the operation of the plant, the operating head of 108 ft. making the tail-race work which came just at the ends of the draft tubes, particularly difficult; the construction of a reinforced highway bridge over the penstocks and the widening of the canal for several hundred feet, also had their difficulties, but to a less degree. Of Mr. Dakin's office work may be mentioned the design and estimates for a 4 000-kw., 40-ft. head, hydro-electric plant, and appraisals of the power plants, car-houses, and other buildings and structures of the trolley line between New London and the Massachusetts State Line, of the entire property

* Memoir prepared by Charles Rufus Harte, M. Am. Soc. C. E.

of the Westport Water Company, and of many smaller groups of trolley properties of The Connecticut Company.

Successively filling positions of steadily increasing responsibility, Mr. Dakin's work came to the attention of the interests which had just purchased the Housatonic Power Company for the New York, New Haven, and Hartford Railroad, and, in April, 1917, he went with them, successfully handling the purchase of much right of way and the adjustment of changes of highways and bridges, necessary for the construction of a 75-ft. head, 24 000-kw. capacity, hydro-electric plant on the Housatonic River, at Stevenson, Conn. Later, when construction started, Mr. Dakin was transferred to the J. A. P. Crisfield Contracting Company, and, as Assistant Engineer, had charge of all surveys, maps, and highway changes, the latter involving a number of country roads and some State highways. In connection with the latter, Mr. Dakin constructed over the Pomperaug River a reinforced concrete cantilever bridge of arch form, with a central span of 90 ft., and semi-arches 45 ft. long on either side, the design being the joint work of Mr. Dakin and R. L. Saunders, Deputy State Highway Commissioner of Connecticut. The pool, 10 miles in length, fills a narrow valley with steep hills and deep intersecting ravines on each side, making surveys difficult and the determination of the economic relocation of the disturbed highways a problem calling for engineering ability of high order, while the natural difficulties of the field work were greatly increased by the fact that most of it had to be done during the severe winter of 1917-18.

Mr. Dakin was completing this work, and had organized the forces and was directing the surveys of other power and storage projects, when, after a very brief illness, he died at Danbury, Conn., on December 15th, 1918, a victim of the influenza epidemic of that winter. On September 13th, 1913, he was married to Marion Evans, of Gaylordsville, Conn., who, with a son, Theodore, born on November 11th, 1916, survives him. Another son, Edward, born on January 28th, 1918, and Mrs. Dakin's mother died within a few hours of Mr. Dakin.

"Rob" Dakin, as he was best known to his friends, was a man of engaging personality, combining to a rare degree technical ability, executive capacity, and a "sunshiny" disposition next to impossible to ruffle. Although cut down at little more than the beginning of a career of great promise, he left no small monument in good work well done, and in the hearts of his friends an undying memory.

Mr. Dakin was elected a Junior of the American Society of Civil Engineers on December 2d, 1914, and an Associate Member on January 15th, 1917.

STANLEY DEAN, Assoc. M. Am. Soc. C. E.*

DIED OCTOBER 2D, 1918.

Stanley Dean, the son of John Dean and Elizabeth Stevenson Findlaw Dean, was born in Manchester, England, on February 22d, 1879.

At the age of nine he came to the United States with his parents, his father being engaged in engineering contracting at that time. His education was obtained in various schools, mostly in the South and West, as his father's business necessitated moving from place to place.

In 1901 he entered Washington University, St. Louis, Mo., where he remained two years. The family then settling in Chicago, Ill., Stanley entered the Civil Engineering Department of the Armour Institute of Technology, from which he was graduated in 1905 and received the degree of Civil Engineer in 1910.

The following record of Mr. Dean's professional experience is taken from his application for a commission in the Quartermaster Corps, U. S. Army:

1900-05, Timekeeper, Material Clerk, Carpenter, and Concrete Foreman, successively, during all of 1900 and to September, 1901; during the summers of 1902-03-04, on construction of concrete arches, culverts, abutments, piers, and earthwork incidental to double-tracking the Grand Trunk Western Railway. In 1905, Superintendent of Construction, for John Dean and Company, of Sixth Avenue Arch Bridge, Des Moines, Iowa. In December of the same year superintended the construction of abutments and culvert at Muir, Mich., for the Grand Trunk Western Railway. In 1906, in the employ of Hugh L. Cooper, M. Am. Soc. C. E., as Draftsman and Designer on parts of McCall Ferry and Keokuk water-power developments, made surveys and gaugings of Trent River, at Healeys Falls, Ontario, and was Transitman on topographical surveys for water-power developments at Schaghticoke and Johnsonville, N. Y.; in charge of reconnaissance work for water power on Connecticut River and East Canada Lakes, New York, and Engineer in Charge of location, surveys, and borings for foundations, etc., at Schaghticoke, N. Y. In 1907, Engineer in Charge of preliminary surveys and investigations, Ingham Mills water-power development, East Canada Creek, New York, and made a similar survey and investigation on Broad River near Columbia, S. C.; April, 1907, engaged on coffer-dam and stone cribwork investigation for proposed 125-ft. concrete dam foundations, East Creek, New York; May, 1907, engaged on Broad River surveys, South Carolina; June-August, 1907, East Creek investigations; September-December, 1907, Resident Engineer

* Memoir prepared by Alfred E. Phillips, M. Am. Soc. C. E.

in charge of field engineering work, assisting Superintendent of Construction in development of water power at Schaghticoke, N. Y., 20 000 h. p., 150-ft. head. This work involved building an ogee gravity dam averaging 25 ft. high, 700 ft. long, in solid concrete, together with intakes, canal, ½ mile long, 120 000 cu. yd. of earth and rock excavation, 12-ft. riveted steel pipe line, 800 ft. long, steel surge-tank, penstocks, and power-house, 56 by 110 ft., for four units, the cost of the work being $1 250 000. In 1908 was engaged on above described work. January-April, 1909, in a similar position, finishing water-power development at Johnsonville, N. Y., 4 000 h. p.; May-August, 1909, Superintendent of Construction on water-power development, Fountain Falls, Montreal River, Ontario, until abandonment of work due to consolidation of companies; then Engineer on construction of Ragged Chutes transmission lines, and spiral riveted pipe carrying compressed air to Cobalt Mining camp; made report on Matabitchouan River development. All the foregoing water-power work was done in the employ of Viele, Blackwell, and Buck, of New York City.

In 1910, Mr. Dean was appointed Instructor in Civil Engineering at the Armour Institute of Technology, having charge of instruction in hydraulics, water power, reinforced concrete, and general construction methods and costs. In 1912 he was made Assistant Professor of Civil Engineering, and, in 1917, Associate Professor of Hydraulic Engineering.

During the summer of 1912 Professor Dean was engaged as Resident Engineer for Solomon, Norcross, and Keis, at Watervliet, N. Y., on the construction of a 100-ft. earth dam for the storm-sewer system. During the summer of 1913 he was associated with the writer in the design and supervision of construction of a hollow concrete dam on a sand foundation, at Hamlin Lake, Michigan.

From June to October, 1917, Professor Dean was Principal Assistant to the Supervising Engineer, Department of Constructing Quartermaster, at Camp Jackson, Columbia, S. C., in charge of all surveys and layout work for topography, roads, railroad track and yards, buildings, sewers, water supply, etc.; and, from July to October, he was in charge of the engineering design and supervision of construction of water lines, reservoir of reinforced concrete having a capacity of 1 250 000 gal., pumping station, 30 miles of sewers, septic tank, and other incidental structures. Professor Dean returned to the Armour Institute of Technology in October, 1917, remaining until January, 1918, when he resigned to become Principal Assistant to the Supervising Engineer, Department of Constructing Quartermaster, Camp A. A. Humphreys, Accotink, Va., in charge of railroad location, general surveys, and dock construction.

He received a Captain's commission on August 24th, 1918, and was then made Supervising Engineer in the Constructing Quartermaster Corps at Camp Humphreys, Va. He was supervising the building of a dam and power plant at Springfield, Va., in connection with Camp Humphreys, when, on October 2d, 1918, he was instantly killed at a railroad crossing.

He was in an automobile on his way to the dam at Springfield. A colored chauffeur was with him, but Capt. Dean was driving at the time. The crossing at this place is very dangerous, the view of the tracks being obstructed. He had waited for a train to pass and then started across the tracks only to be caught by a fast train from the opposite direction. The chauffeur jumped and escaped without injury, but Capt. Dean, in trying to save himself and the car, stalled the engine and then jumped to save himself. He was struck and thrown 100 ft., and instantly killed.

As a student, instructor, engineer, and a man among men, Stanley Dean was one in a thousand. Absolutely honest, upright, clean mentally and morally, he commanded the love and respect of all with whom he came in contact. He possessed a keen, analytical mind, infinite patience, and ability of concentration that was reflected in whatever he undertook. He loved to teach, and his professional experience, combined with up-to-date knowledge of his specialty, made him an ideal instructor.

He was married on December 14th, 1913, to Miss Ellen Hallaway, of Schaghticoke, N. Y., who, with a daughter, survives him.

Capt. Dean was elected an Associate Member of the American Society of Civil Engineers on April 1st, 1908.

JOHN HULL DECKER, Assoc. M. Am. Soc. C. E.*

DIED OCTOBER 10TH, 1918.

John Hull Decker was born in Sioux City, Iowa, on September 25th, 1878. The family moved to Brooklyn, N. Y., where Mr. Decker attended the public schools, and was graduated from the Manual Training High School in 1898. During the summers of 1895, 1896, and 1897 he was employed in the shops of the Thomson Meter Company, of Brooklyn, assisting in experiments on water meters, and, in 1898, he took up the study of surveying in the office of Mr. Charles Crook, of Brooklyn, and afterward with Mr. R. L. Williams, of the same place, first, as Rodman and then as Instrumentman. In January, 1900, he entered the employ of the late Richard Lamb, M. Am. Soc. C. E., of New York City, and was in responsible charge of topographical surveys for electric railways, water mains, sewers, and road construction, and assisted in the design and construction of a copper mining plant.

Throughout 1901, Mr. Decker was with the Babcock and Wilcox Company, of Bayonne, N. J., as Draftsman on water-tube boilers, Inspector on the erection of factory buildings, and Engineer, Inspector, and Surveyor on switchyard work.

In January, 1902, he entered the employ of the Atlantic City Sewerage Company, Atlantic City, N. J., as Engineer on construction for three months and then as Superintendent and Engineer of the company, having responsible charge of the design, construction, and maintenance of the sewerage system, involving re-designing, enlarging, and reconstructing the system, comprising about 50 miles of pipe sewers.

From January, 1906, until his death, Mr. Decker was Engineer and General Manager of the Atlantic Construction and Supply Company, of Atlantic City, engaged in general contracting, particularly of sewerage systems, water-works, highway construction, and reinforced concrete work. His work as Contractor in the erection of the new electric light power plant at Atlantic City attracted favorable attention. He also built the new Somers Point-Longport Boulevard. Probably his most notable work, apart from that of rebuilding the Atlantic City sewerage system, was done in connection with T. Chalkley Hatton, M. Am. Soc. C. E., on the design and construction of the Atlantic City drainage canal.

Mr. Decker was a self-made man and engineer, well known all over South Jersey and in many other communities. He was affable and

* Memoir prepared by F. Herbert Snow, M. Am. Soc. C. E.

whole-souled, and his friendship was valued. Although cut off in the prime of life, and at a time when the business for which he had struggled had become well established, and with bright prospects ahead, he left an estate that will provide comfortably for his widow and child.

Mr. Decker was elected a Junior of the American Society of Civil Engineers on September 6th, 1904, and an Associate Member on December 5th, 1906.

GUSTAVO ADOLFO DUBOIS, Assoc. M. Am. Soc. C. E.*

DIED AUGUST 30TH, 1918.

Gustavo Adolfo Dubois was born at Matanzas, Cuba, on September 25th, 1882. He was a graduate of the Massachusetts Institute of Technology, having received, in June, 1908, his degree of B. S. in Civil Engineering.

After his graduation, Mr. Dubois returned to Cuba and entered the employ of the Public Works Department of the City of Havana, as Assistant Engineer in the Department of Civil Construction. In October, 1909, he was appointed Resident Engineer in charge of water-works construction at Cienfuegos, Cuba. As such, he had immediate supervision over the construction of the 10 000 000-gal. reinforced concrete reservoir for the storage of the city water supply, work representing an outlay of $240 000, and also directed the survey and design of various other structures in connection with the new water-works.

From Cienfuegos, Mr. Dubois was called to Havana as Assistant Engineer in charge of sewer and drain construction under D. E. McComb, M. Am. Soc. C. E., then Chief Engineer of the Department of Sewers and Paving of the City of Havana, starting on his new duties in September, 1910. He was closely associated with the work of designing and constructing the sewerage system of the entire city, the cost of which amounted to about $15 000 000. He remained with the Department for three years, until September, 1913, when, the work of construction being nearly finished, he accepted, at the special request of the late Dr. Enrique Nuñez, then Secretary of Health of the Republic of Cuba, an appointment as Chief Engineer of the Sanitary Department of the Republic.

Mr. Dubois' early connections with sanitary projects and construction, and his specialization in Sanitary Engineering while at college, well fitted him for his new responsibilities, and it was a credit to his efficiency and executive ability that, in spite of several political changes, he was able to win the confidence of the successive Administrations under which he was called to serve. During his connection with the Sanitary Department of Cuba, he was influential in helping to maintain the high degree of sanitary standards which have placed the largest cities of the Island, Havana especially, among the most healthful in the world.

In February, 1918, Mr. Dubois resigned his position with the Sanitary Department, to accept the management of one of the leading industrial concerns of Havana, the "Tropical" Brewery, pertaining to the Nueva Fábrica de Hielo, a company owning and operating the

* Memoir prepared by G. A. Hernández, Esq., Havana, Cuba.

two largest breweries on the Island. He had hardly started on his new duties when, after a short illness, he died on August 30th, 1918.

Mr. Dubois was one of the leaders of the young generation of Cuban engineers who, educated at the leading American universities, have contributed so much toward the development of Cuba's resources, making this little Island one of the most prosperous in the world. His early death, at the time when success was beginning to crown his untiring efforts, will be regretted by all who had had personal contact with him and could appreciate the sterling qualities of his character.

Mr. Dubois was married in 1909, to Miss Rita M. Lavastida, of Matanzas, Cuba, who, with a daughter and his mother, survives him.

He was a Member of the Cuban Society of Engineers, and also held the degree of Civil Engineer from the University of Havana.

Mr. Dubois was elected a Junior of the American Society of Civil Engineers on September 1st, 1908, and an Associate Member on May 6th, 1914.

CLARENCE FREDERICK EBERLY, Assoc. M. Am. Soc. C. E.*

DIED DECEMBER 18TH, 1918.

Clarence Frederick Eberly was born at Perrysburg, Ohio, on November 30th, 1882. He received his early education in the grade and high schools of Perrysburg, and, on his graduation from Ohio State University in June, 1906, entered the service of the United States Government as Junior Topographer in the United States Geological Survey. He gave a course of engineering instruction at the Harvard Engineering Camp, in the summers of 1909, 1910, and 1911, which gained for him the praise of Hector J. Hughes, M. Am. Soc. C. E., the Director of the camp. He remained in the Survey Service until November, 1912. During Mr. Eberly's connection with that department he had charge of various work, including the mapping of 225 sq. miles in West Virginia, making topographic surveys in Idaho and Arizona, the making of a map of Seattle for the Alaska-Yukon and Pacific Exposition, besides considerable office work which was done at the headquarters of the Survey, in Washington, D. C.

Mr. Eberly left the Survey Service in November, 1912, to help take charge of the establishing of a geographical survey department for the Argentine Republic, but only spent one year in Argentine, returning in December, 1913, to the United States Geological Survey.

Mr. Eberly left the Survey again in April, 1914, to engage in a real estate and building proposition as Secretary of The Heffelbower Realty Company, of Toledo, Ohio. After successfully putting through this venture, he joined the staff of the Lucas County Surveyor, in May, 1917, as Senior Engineer, in charge of highway surveys and construction, but, in July, 1918, obtained a leave of absence in order to render what aid he could in the construction of the Government Air-Nitrates Plant, then building in Toledo. On this work he had charge of the construction of streets and highways, and, by his untiring efforts and ability, rendered valuable service. He left the Nitrates Plant in September in order that he might be able to donate his services to the Government as Instructor of Field Engineering at the Toledo University for the Student Army Training Corps, and was engaged in this work at the time of his death. While instructing his class he was stricken with an attack of influenza which in three days developed into pneumonia, from which he died in less than one week, on December 18th, 1918.

He was unmarried, and leaves, besides his father and mother, Mr. and Mrs. F. C. Eberly, of Perrysburg, Ohio, two brothers: Somers L.

* Memoir prepared by Cecil L. Rood, Esq.

Eberly, of Toledo, and Capt. Karl C. Eberly, who served with the American Expeditionary Forces in France.

Mr. Eberly was a member of Phœnix Lodge, No. 123, F. and A. M., a member of the Kappa Sigma Fraternity, and was elected an Associate Member of the American Society of Civil Engineers on September 6th, 1910.

WILLIAM WETMORE GIBBS, Assoc. M. Am. Soc. C. E.*

DIED JANUARY 13TH, 1919.

William Wetmore Gibbs was born in Melbourne, Fla., on January 12th, 1889. From his earliest years he had a marked taste for constructive work and applied science, and this led him to take up the study of Civil Engineering, in spite of a great many difficulties. He entered the University of Florida in 1905, worked his way through by his own energy and industry, and was graduated in 1909 with the degree of B. S. C. E., having been the first graduate in Civil Engineering from that University. His record as a student was one of brilliant achievement in his studies, combined with prominent activity and leadership in student enterprises. After his graduation he always retained a hearty interest in the University of Florida, frequently visiting it and keeping up his acquaintance among its faculty and alumni.

Immediately after his graduation Mr. Gibbs was placed in charge of a part of the work of planning and laying out the suburb of Jacksonville known as Ortega. A few months later he entered the employment of The Phosphate Mining Company, at Nicholas, in Polk County, Florida, where, on account of his splendid ability, and notwithstanding his youth, he was rapidly advanced through various positions until he became Assistant General Manager of the company and second in charge of this large enterprise.

Immediately on the entry of this country into the World War, he gave up his position, went to Washington for training, volunteered for service in France, was commissioned First Lieutenant, and sent overseas, being attached to the 6th Engineers, Company B. After several months' service, his health broke down and he was invalided home for recuperation. Much to his distress, he was unable again to satisfy the medical officers of his physical fitness for further active service, and, after a few months, he was given an honorable discharge from the Army. Pending his discharge, Lieut. Gibbs threw himself actively into the educational campaigns for Liberty Bonds and Red Cross funds, and, fresh from his experiences in France, was able to speak with very great effectiveness in these campaigns. Immediately on his discharge from the Army, he opened an office as Consulting Engineer at Gainesville, Fla., and quickly developed a successful practice. While engaged on some of his professional work near Green Cove Springs, early in January, 1919, he contracted influenza, from which he died scarcely more than a week later in Jacksonville.

On November 2d, 1910, Mr. Gibbs was married to Miss Lucia Patton, who, with three children, survives him.

* Memoir prepared by Dr. J. R. Benton, Secretary, Florida Engineering Society.

He was not only a man of great native ability and high promise in his profession, but also possessed unusually fine personal qualities. He had to an extraordinary degree the faculty of winning both the good will and the confidence of all with whom he came in contact. It was his temperament to follow with a great deal of enthusiasm whatever he undertook; and this spirit was characteristic of his attitude to his chosen profession, in which he took both pride and pleasure, and for the higher ideals of which he displayed the greatest devotion.

Mr. Gibbs was a charter member of the Florida Engineering Society. In 1916 the University of Florida granted him the degree of C. E. He was a member of the Alpha Tau Omega fraternity and of the Phi Kappa Phi honorary fraternity.

Mr. Gibbs was elected a Junior of the American Society of Civil Engineers on October 7th, 1914, and an Associate Member on May 15th, 1917.

NORMAN MARSHALL HALCOMBE, Assoc. M. Am. Soc. C. E.*

DIED FEBRUARY 15TH, 1919.

Norman Marshall Halcombe, the son of the late Arthur Follett Halcombe, of Fern Grove, Urenui, Taranaki, New Zealand, was born at The Pines, Feilding, New Zealand, on July 29th, 1878.

He attended the public schools in New Zealand, and in August, 1905, he entered Stanford University as a special student. He was graduated, with the degree of B. A. in Civil Engineering, in 1909. While at Stanford University he was engaged in numerous activities, was President of the Stanford Society of Civil Engineers, a prominent member of the Eucina Club, and took part in several dramatic productions.

Mr. Halcombe served as an Apprentice in the Machine Works of David Murray and Company, at Wanganui, New Zealand, from March, 1899, to October, 1900, and then, until November, 1901, as a Machinist (Improver) at the Machine Works of Joseph Sparrow and Son, at Dunedin, New Zealand, on the construction and erection of gold dredges. He served as Foreman and then as Draftsman with Goniuan and Company, Engineers, of Newcastle, New South Wales, from March, 1902, until March, 1905, on colliery plant and machinery. His next work was with the Schäake Machine Works, of New Westminster, B. C., Canada, as a Draftsman on the design of cannery and saw-mill machinery.

He was employed as Draftsman for the Bay Cities Water Company from February, 1906, until July, 1907, on computations, etc., for the Sierra Water Supply for San Francisco, and was then engaged, until August, 1908, as Field Draftsman on the survey of the Yuba and Feather Rivers, and as Instrumentman and in charge of level party for the California Débris Commission. From the latter date until November, 1908, Mr. Halcombe was Chief Draftsman for the Stone Canyon Coal Company, and was engaged in designing head-works, tracks, trestles, bridges, buildings, tipple structure, dam, etc. Then, until September, 1909, he was Contractor's Engineer for the Atlantic, Gulf, and Pacific Company, of San Francisco, in charge of dredging Oakland Harbor, dredging for wharf foundations for Government docks at Fort Mason, San Francisco, and the construction of three bulkhead structures in Oakland Harbor. From September, 1909, until May, 1910, he was Junior Engineer with the City of San Francisco, on the construction of a section of the overflow conduit. He then became Engineer of the Carmen Creek Mining Company, of Salmon, Idaho, and was engaged in the erection of an experimental gold mill.

* Memoir prepared by E. W. Sawyer, Assoc. M. Am. Soc. C. E.

Mr. Halcombe served for five years as Chief Engineer with Messrs. Duryea, Haehl, and Gilman, on large irrigation projects, surveys, compilations of data, computations, design, construction, etc. He was then engaged in private practice in San Francisco for two years.

His action with regard to the World War was very praiseworthy, as he gave up a lucrative practice in San Francisco, and traveled to London at his own expense to offer his services in assisting to defeat the Germans. He joined the Royal Engineers early in 1915, and was commissioned as Second Lieutenant on May 1st of that year. He was promoted to Lieutenant a month later, and gained his Captaincy on August 4th, 1915. He commanded and trained the 31st Cheshire Field Company, R. E., from June 1st to August 20th, 1915, and was then ordered to Gallipoli as Captain with the 21st Welsh Field Company, R. E. At Gallipoli he was transferred and placed in command of the 21st Cheshire Field Company, R. E., and, later, was sent to Egypt on special evacuation work, followed by special transport work in the Western Desert, Egypt and Sinai, for which he was mentioned in dispatches.

Capt. Halcombe joined the Royal Flying Corps on November 1st, 1916, and organized and developed the Engine Repair Depots, in Egypt and Palestine. He did some special work and reported on technical subjects in connection with the Air Service. He received his commission as Major on November 16th, 1917, and was twice mentioned in dispatches.

Maj. Halcombe returned to England on September 1st, 1918, in connection with the liaison work of the Royal Flying Corps then being carried out in the United States. Arriving in London at a time when technical men were scarce, his contemplated trip to America was forestalled, and he was attached for immediate service to the Technical Department, Parachute Section, of Aircraft Production.

At the time the Armistice was signed he was still in this position, as Major in the Royal Engineers and the Royal Air Force. He expected to return to San Francisco to re-open his business there in connection with the firm of Halcombe, Flanders, and Read, but was offered an important staff position on the Indian Establishment of the Air Force in India, and made arrangements to sail for India, on January 23d, 1919. On the day before he sailed, he was married at St. Mary's, Battersea, to Miss Blanche Stuart, eldest daughter of Wesley and Amy Turton, of "Hawkshead", Lake Wakatipu, New Zealand. Mrs. Halcombe followed her husband on the next boat. He was attacked with influenza and pneumonia on the voyage, and at Port Said was removed from the steamer to the Red Cross Hospital in a very weak condition from which he did not recover, but passed away on February 15th, 1919.

Maj. Halcombe is survived by Mrs. Halcombe, who has returned to her home in New Zealand; a brother, A. H. Halcombe; and two sisters, Mrs. M. A. Taylor and Mrs. M. L. Gordon Glassford.

"Joe", as he was familiarly called by his associates, was a great favorite, especially among his engineering friends. He had a quick wit and a thorough appreciation of a joke. He had a high conception of the duties of an engineer, and as he was absolutely thorough in everything he did, his judgment in engineering as well as in personal matters was relied on by all who were in close touch with him. His sacrifice in the war is a monument to his conscientiousness, and the example he has set will not soon be forgotten. He will be sincerely missed by his many friends and by all who were privileged to know him.

He was a valuable member of the Press Club, of San Francisco, and, on leaving in 1915 to join the English forces, his fellow-members made him an Honorary Member.

Maj. Halcombe was a member of the Western Society of Engineers, and of several clubs in London. He was elected a Junior of the American Society of Civil Engineers on September 3d, 1907, and an Associate Member on May 2d, 1911.

ROBERT DWIGGINS MONTEITH HENLEY, Assoc. M. Am. Soc. C. E.*

DIED MAY 3D, 1918.

Robert Dwiggins Monteith Henley was born near Richmond, Ind., on February 15th, 1879.

During his summer vacations of 1898 and 1899, Mr. Henley was employed as Rodman with the Cleveland, Cincinnati, Chicago, and St. Louis Railway Company.

In October, 1899, he entered the employ of the Louisville and Nashville Railroad Company, as Draftsman in the Mechanical Department. He remained with this Company until November, 1904, serving as Draftsman in the Chief Engineer's Office, Assistant to the Resident Engineer, Resident Engineer, and Assistant Engineer on the Pensacola, the Pensacola and Atlantic, the Birmingham, Selma, and New Orleans, and the Southern Alabama Divisions, of that Company.

From December, 1904, to May, 1905, Mr. Henley was a student at the Central University of Kentucky, but returned to the Louisville and Nashville Railroad Company as Draftsman in the Chief Engineer's office. During September and October, 1905, he was employed as Draftsman in the Bridge Engineer's office of the Cleveland, Cincinnati, Chicago, and St. Louis Railway Company.

In October, 1905, Mr. Henley entered the service of the Chicago, Rock Island, and Pacific Railway Company, and, until April, 1906, was engaged as Resident Engineer for the Morris Terminal Railway Company. From April to June of the same year, he served as Assistant Engineer in charge of the construction of the Morris Terminal Railway and the Kaw River Bridge, at Kansas City, Mo., and, from June, 1906, to February, 1907, he was employed as Assistant Engineer in charge of the Rose Hill Coal Spur near Oskaloosa, Iowa. After the contractors had finished their work, Mr. Henley had charge of the organization of the force to move about 80 000 cu. yd. of material, of which about 30 000 cu. yd. was classified. From March to October, 1907, he served as Transitman on location and as Estimator for proposed grade reduction work for the Railway Company.

In October, 1907, Mr. Henley left the service of the Chicago, Rock Island, and Pacific Railway Company to enter Earlham College, Richmond, Ind., as a special student, where he remained until May, 1908. At that time, he was employed as Building Superintendent for the Murry Sun Amusement Company, in charge of the construction of the Murry Theater at Richmond, Ind.

In August, 1908, he entered the employ of the Atchison, Topeka, and Santa Fé Railway Company as Building Inspector, and also as Designer of reinforced concrete work, with headquarters at Topeka,

* Memoir prepared from information on file at the Headquarters of the Society.

Kans. Mr. Henley retained this position until 1912, when he went to the Kansas City Southern Railway Company. While with this Company he was connected with the work of the Chief Engineer's office, at Kansas City, Mo.

In 1913, Mr. Henley accepted a position as Assistant Engineer with the Central Coal and Coke Company of Kansas City, Mo., which position he held at the time of his death which occurred on May 3d, 1918. While with this Company, he was engaged in the design and supervision of various improvements around its mines, yards, and saw-mills.

He was a comparatively young man, and with his wonderfully brilliant mind and his wide experience in the various branches of engineering, he no doubt would have attained an eminent position in the Engineering Profession, had he lived.

Mr. Henley was elected a Junior of the American Society of Civil Engineers on September 3d, 1901, and an Associate Member on January 31st, 1911.

BRUCE RITCHIE HONEYMAN, Assoc. M. Am. Soc. C. E.*

DIED OCTOBER 5TH, 1918.

Bruce Ritchie Honeyman was born at Portland, Ore., on December 30th, 1885, of Scotch parentage. He received his early schooling at the Portland Academy, from which he went to the Massachusetts Institute of Technology and was graduated from there in 1906.

On his return to Portland, Mr. Honeyman was employed as Structural Engineer with Morris H. Whitehouse, Architect, and remained with the firm for some years. He then went with the Hurley-Mason Company as Structural Engineer, designing and superintending the construction of several buildings. He left this Company to go to work in Vancouver, B. C., Canada, for the Norton-Griffiths Company. After the completion of his work there, Mr. Honeyman went to St. Paul, Minn., and, for eleven years, was employed as Engineer by the F. J. Romer Construction Company. At the time of his entry into the military service, he held the position of Manager of General Contracting and Construction for the Company.

On May 11th, 1917, Mr. Honeyman entered the military training camp, at Fort Snelling, Minn., as a civilian candidate for a commission in the Engineers. He was transferred later to the Central Training Camp for Engineers, at Fort Leavenworth, Kansas, where he was assigned for instruction to the 13th Provisional Training Regiment. He served with this regiment as a candidate until August 14th, 1917, when he was graduated. On August 15th, 1917, he was commissioned as Captain of Engineers, United States Army, and assigned to duty at Camp Dodge, Iowa, with the 313th Engineers, in command of Company A.

Capt. Honeyman proceeded overseas with his regiment during the early part of September, 1918, and served with it until September 28th, 1918, at which time he was confined to quarters on account of sickness which later developed into pneumonia, resulting in his death on October 5th, 1918. Maj.-Gen. W. M. Black, M. Am. Soc. C. E., Chief of Engineers, states concerning Capt. Honeyman's service with the United States Army: "His services were satisfactory in every respect," and it would seem to those who knew him that these words express the opinion of his work throughout his entire career.

In June, 1909, he was married to Marion Blakely, of Tacoma, Wash. He is survived by a daughter, Elinor, and a son, Blakely.

Capt. Honeyman was elected an Associate Member of the American Society of Civil Engineers on September 5th, 1911.

* Memoir prepared by George C. Mason, M. Am. Soc. C. E.

PAUL ROBERT KIRSTEIN, Assoc. M. Am. Soc. C. E.*

DIED OCTOBER 17TH, 1918.

Paul Robert Kirstein was born at Cincinnati, Ohio, on April 20th, 1888. He finished his preparatory course for college in the Technical School of the University of Cincinnati in 1905, and, in 1909, he was graduated from Purdue University, receiving the Bachelor of Science Degree in Civil Engineering.

Mr. Kirstein's first work was with the United States Coast and Geodetic Survey as Topographical Draftsman, which position he retained for three months.

In 1909, he entered the Engineering Department of the City of Cincinnati, where he remained until 1916. His first work was with the Highway Division and, later, with the Sewer Division. In 1911, he was transferred to the Division of Structures where he was engaged on the design of various small works such as concrete steps, culverts, bridges, etc. In 1912, he was appointed Inspector of reinforced concrete work on the Gilbert Avenue Viaduct, a structure costing about $250 000. During 1913 and 1914, Mr. Kirstein was employed as Assistant Resident Engineer on the Ludlow Avenue Viaduct, a reinforced concrete structure costing about $350 000, and in 1915 and 1916, he served as Resident Engineer on the Hopple Street Viaduct, a reinforced concrete structure costing about $430 000. After finishing this work, he was engaged on the design of various concrete structures, the principal one of which was the McMillan Street Bridge, estimated to cost about $150 000.

When the work of planning the proposed rapid transit system for the City of Cincinnati was commenced in 1917, Mr. Kirstein was appointed Designing Engineer for the Board of Rapid Transit Commissioners. His work in this connection was on the design of the various structural features such as subway, reinforced concrete elevated structure, trestles, etc. He held this position at the time of his death.

Mr. Kirstein was a very capable and energetic young man, of high character and pleasing personality. His untimely death closed a promising career and was a distinct loss to the Engineering Department which he served.

He was married, on September 26th, 1914, to Miss Freda Kohstall, of St. Bernard, Ohio, who, with a son, survives him.

Mr. Kirstein was elected an Associate Member of the American Society of Civil Engineers on May 15th, 1917.

* Memoir prepared by Frank L. Raschig, M. Am. Soc. C. E.

ANGUS ROBERT MACKAY, Assoc. M. Am. Soc. C. E.*

DIED JUNE 29TH, 1918.

Angus Robert Mackay, the eldest son of the late Senator Robert Mackay, was born at Montreal, Que., Canada, on October 27th, 1872. After his preparatory education, he entered the Massachusetts Institute of Technology, from which he was graduated in Mining Engineering in 1894. During 1894 and 1895, he studied at the Berg Academie and the University of Berlin, Germany.

On his return to the United States in 1895, Mr. Mackay was employed by the Horseshoe Mining and Milling Company, of Deadwood, S. Dak., as Manager of its mining interests and of its reduction plant, the Kildonan Mill, at Pluma, S. Dak. He retained this position until the property was sold in 1901.

From 1902 to 1904 he was engaged in research work and study for mining interests at Sault Ste. Marie, Ontario and Michigan, and also at Sydney, Nova Scotia.

In 1904 Mr. Mackay joined the Engineering Staff of the Electrical Development Company of Ontario, at Niagara Falls, Ont., Canada, on one of its large hydro-electrical projects. He also had charge during this time of some hydraulic surveys and investigations near Lake Superior for Hugh L. Cooper, M. Am. Soc. C. E.

From 1906 to 1907 he was identified with, and had an interest in, a foundry enterprise near Montreal, Que., Canada; and, from 1907 to 1908 was engaged as Advertising Manager for the Canadian Fairbanks Company, with headquarters at Montreal.

In 1908 Mr. Mackay entered the employ of the General Exploration Company, of Boston, Mass., and was sent by that Company to Wickenburg, Ariz., as Manager of the Vulture Mine. He supervised the construction of a 20-stamp mill and a cyanide plant, and developed the property into a successful business. He retained this position until his death, which occurred suddenly at Oakland, Cal., on June 29th, 1918.

Mr. Mackay's activities were numerous and varied; he was particularly interested in the development of the natural resources of Arizona. To his friends and business associates, who were many, his death came as a shock, and he will be greatly missed by all who knew him and worked with him. He had been a member of the American Institute of Mining Engineers since 1896.

Mr. Mackay was elected an Associate Member of the American Society of Civil Engineers on October 29th, 1912.

* Memoir prepared from information on file at the Headquarters of the Society.

HUNTER McCLURE, Assoc. M. Am. Soc. C. E.*

DIED SEPTEMBER 26TH, 1918.

Hunter McClure, the son of Hunter H. McClure and Alice Camp McClure, was born in Rome, Ga., on December 23d, 1887.

After his preparatory education, he entered the Georgia School of Technology from which he was graduated in June, 1908, with the degree of B. S. in Civil Engineering. He then entered Cornell University and because of his previous engineering experience during his vacations and his advanced credits, he was granted the degree of Civil Engineer in June, 1910.

From September, 1909, to September, 1910, Mr. McClure was engaged on railroad work as Transitman on valuation surveys on the lines of the Central of Georgia Railway Company in Alabama; Chainman and Field Draftsman for the Oregon Short Line Railroad Company on preliminary surveys and location in Utah, Oregon, and Idaho; and as Inspector on the construction of reinforced concrete snowsheds in the Cascade Mountains, for the Great Northern Railway Company.

In September, 1910, he returned to Cornell University as Instructor in the Mechanics of Engineering at Sibley College; he also did post-graduate work in railway, bridge, and hydraulic engineering.

From June, 1911, to February, 1912, Mr. McClure was in the employ of the American Bridge Company as Draftsman on shop detail drawings of steelwork for mill and office buildings, schools, hotels, etc., having been stationed at the Company's Pencoyd and Brooklyn plants and in the New York office.

In March, 1912, he returned to the West, where he spent two months in the offices of the Northern Pacific Railway Company, at St. Paul, Minn., and Tacoma, Wash. He then entered the service of the Idaho Northern Railway Company, and was employed until March, 1913, as Instrumentman and Inspector on the construction of the Payette River Bridge.

In March, 1913, Mr. McClure returned to the American Bridge Company as Draftsman at its Gary Plant, but remained only until July, when he was appointed Draftsman in the Bridge Department of the Chesapeake and Ohio Railway Company, and was engaged on bridge design, the design of roadway structures, plans for the construction of tidewater coal piers, etc.

He remained with this company until October, 1914, when he accepted a position with the Division of Valuation, Interstate Commerce Commission, and was sent to the Pacific District. After a month or so in the San Francisco office, Mr. McClure was made Assistant Field Engineer in charge of a field party, which position he

* Memoir prepared from information on file at the Headquarters of the Society.

resigned in December, 1917, to enlist in the Reserve Engineer Corps, then being organized for service in the World War.

He was commissioned a First Lieutenant and trained at Camp Lee, Va. He was afterward assigned to Company N, 21st Engineers, and spent some time at Camp A. A. Humphreys, Va., from which place he was sent with his regiment to France in 1918. After his arrival in France, he was taken suddenly ill, with spinal meningitis on September 25th, 1918, and died the following day.

Lieut. McClure was elected a Junior of the American Society of Civil Engineers on January 4th, 1910, and an Associate Member on October 9th, 1917.

WILLIAM MENKE, Assoc. M. Am. Soc. C. E.*

DIED NOVEMBER 1ST, 1918.

William Menke, the son of John and Louise Sommers Menke, was born at New York City, on December 2d, 1885. His early education was received in the public schools of New York, and, in 1904, he entered Columbia University, from which he was graduated with the degree of Civil Engineer in 1908.

Immediately after his graduation, Mr. Menke was employed as Draftsman and Transitman, on the construction of a 2 000-h. p., hydro-electric plant at Walden, N. Y.

In February, 1909, he entered the employ of the New York Board of Water Supply as Engineering Inspector in the Reservoir Department, in connection with the construction of the Catskill Aqueduct. After about one year as Inspector, at Brown's Station, Mr. Menke was appointed an Assistant Engineer with the Water Board, and transferred to the Southern Aqueduct Department near White Plains, N. Y. While in this Department he was in charge of the field work on the construction of the concrete cut-and-cover aqueduct, steel pipe siphon, and gate-chambers, at Scarsdale, N. Y. He was engaged for about two years in this work. He was then transferred to the City Aqueduct Department, in the Manhattan Division, and was employed on the construction of a 48-in., cast-iron main and, subsequently, on two shafts and the tunnel from 23d Street to 42d Street, New York City.

In August, 1914, Mr. Menke left the Water Board and received an appointment as Engineer with the New York Public Service Commission, First District, on subway construction in New York City. He was in the Commission's employ for two years as Assistant to the Section Engineer, having had charge of the field parties and office work on the construction of the Lexington Avenue line between 43d and 53d Streets. The work on this section, valued at more than $2,000,000, consisted of a four-track, steel and reinforced concrete structure, which was built partly in open cut and partly in tunnel. To the regret of his associates, he resigned in August, 1916, to accept a position as Draftsman and Designer with the Bethlehem Steel and Bridge Company, at its plant in Steelton, Pa.

Mr. Menke's next move carried him back to New York City, where, in June, 1917, he entered the employ of the J. G. White Engineering Corporation. For the first few months, he was engaged as Designer and Draftsman in the New York office, and was then sent to Kingston, N. Y., where he was Assistant to the Resident Engineer and, later, Resident Engineer, on a 50-mile, 60 000-volt, transmission line.

* Memoir prepared by Ralph E. Drake, Assoc. M. Am. Soc. C. E.

In June, 1918, Mr. Menke accepted a position as Field Engineer with the Construction Department of The Babcock and Wilcox Company, at its plant in Barberton, Ohio. Activities here consisted of alterations and improvements to existing buildings, the erection of a new machine shop, the installation of electric cranes and other machinery, and improvements and reconstruction work on plant railroad lines, craneways, etc. Mr. Menke's duties were arduous, but he always performed them with a willing and cheerful spirit. This, his last, position as Engineer on industrial plant construction, was one for which he felt he was particularly fitted and in which he was best satisfied to work.

Mr. Menke's work was always well and carefully done, and he was held in high esteem by his numerous associates, both for his valuable, painstaking, faithful services and his pleasing personality. His quiet, unassuming nature and his consideration for others endeared him to all with whom he came in contact.

He died on November 1st, 1918, at the Citizens' Hospital, Barberton, Ohio, a victim of influenza followed by pneumonia, his death having occurred after an illness of one week. He was unmarried.

Mr. Menke was elected a Junior of the American Society of Civil Engineers on December 6th, 1910, and an Associate Member on April 16th, 1918.

OGDEN MERRILL, Assoc. M. Am. Soc. C. E.*

DIED OCTOBER 5TH, 1918.

Ogden Merrill was born in the old Williamsburg section of Brooklyn, N. Y., on December 9th, 1877. His father was one of the founders of Merrill Brothers, which firm was originally located at Grand Street, New York City, as a ship chandlery, in the old days when sailing vessels were still common along the wharves on the East Side. This firm is still in existence, but is now engaged in the manufacture of drop forgings. Mr. Merrill's father is still alive, hale and hearty at 89 years.

Mr. Merrill received his education at the Boys High School, Brooklyn, and at Cornell University, from which he was graduated in the course of Civil Engineering, in 1899.

After graduation, Mr. Merrill entered the employ of the late Ira A. Shaler, M. Am. Soc. C. E., acting as an Assistant Engineer and Superintendent on the construction of the rock tunnel under Park Avenue, New York City, for the Rapid Transit Commission, during the construction of which Mr. Shaler lost his life. Mr. Shaler was noted for his policy of surrounding himself with young engineers, who received their early training under his supervision. Many of those who were graduated from this practical school are now engaged in the construction business for themselves.

After the completion of the foregoing work, Mr. Merrill was employed by the United Engineering and Contracting Company as Engineer and Superintendent, in charge of the construction of the electric pumping station for the dry docks of the New York Navy Yard, the placing of the deck on the elevated structure of the Atlantic Avenue Improvement, Brooklyn, and the bridge over Croton Lake for the Putnam Division of the New York Central and Hudson River Railroad.

Later, Mr. Merrill was Superintendent on the construction of the North River Tunnels of the Pennsylvania Railroad, in New York City, and completed the East River Tunnels of the New York Subway system under Mr. T. J. Brown.

In 1908, Mr. Merrill associated himself with Mr. Albert Ruckgaber in the formation of the Merrill-Ruckgaber Company, Constructing Engineers. Under Mr. Merrill's supervision, as President, this Company has been engaged on numerous projects, confining itself principally to heavy masonry construction and pneumatic work, among the more important of which are the following: Depressed boiler house for the Westchester County Court House at White Plains, N. Y.; pneumatic foundations for the Assay Office, New York City; concrete bridges for the Delaware, Lackawanna and Western Railroad, the Long Island Railroad, and the Central Railroad of New Jersey;

* Memoir prepared by Albert Ruckgaber, Esq.

concrete coal pockets for the Central Railroad of New Jersey; water supply system for the City of Cumberland, Md., including a large concrete dam and pipe line; and pneumatic pier foundations for bridges at Chattanooga, Tenn., and Lawrence, Mass.

Mr. Merrill was the inventor of a method of sinking piers and caissons by the use of a system of nested shaft liners, adapted to be expanded telescopically downward by jacking, as the excavation proceeds. This method he patented and used successfully in sinking caissons for the foundations of the Assay Office Building.

Mr. Merrill left for his summer place at Mountainville, N. Y., on September 27th, 1918, in good health. He apparently carried with him the germs of influenza, which, soon after his arrival at Mountainville, developed into a very virulent form, finally resulting in pneumonia. He died on October 5th, after an illness of only six days.

He was married in 1903 to Miss Laura Ruckgaber, of Brooklyn, N. Y., who, with two children, survives him.

He was noted, among those who knew him best, for his novel and ingenious methods of construction, based on sound engineering principles and carried out by him with marked success. He had a very practical strain, and was an authority on all questions relating to sub-surface and sub-aqueous construction. His upright character and lovable disposition, together with his policy of dealing fairly with men in all walks of life, endeared him, not only to a host of friends, but to those who served under him.

Mr. Merrill was elected an Associate Member of the American Society of Civil Engineers on February 3d, 1904.

ADELBERT PHILO MILLS, Assoc. M. Am. Soc. C. E.*

DIED OCTOBER 20TH, 1918.

Adelbert Philo Mills was born in Tecumseh, Mich., on November 10th, 1883. His parents were Mr. and Mrs. Adelbert Wortman Mills. He was educated in the public schools of Tecumseh, having been graduated from the High School in 1902. He entered the University of Michigan the same year, and was graduated in 1906, with the degree of Bachelor of Science in Civil Engineering; he received the advanced degree of Master of Science in 1909.

From May, 1906, until May, 1907, Mr. Mills was an Assistant Instructor in the University of Michigan, and also Assistant in the office of C. G. Wrentmore, M. Am. Soc. C. E., in Ann Arbor, Mich., for whom he designed, estimated, and inspected the construction of several buildings in Ann Arbor, and a reinforced concrete factory building in Jackson, Mich. He also had field charge of the survey of eighty city lots.

From May, 1907, until October, 1908, Mr. Mills was Assistant Engineer of the American Bottle Company, of Newark, Ohio, and was employed on the construction of new glass plants at Newark, and at Streator, Ill. These plants included a reinforced concrete warehouse and power-house, a large factory building, glass furnaces, gas producers, water, gas, and steam piping, electric wiring, conveying equipment, etc., and, on a large part of this work, he was in responsible charge.

From October, 1908, until October, 1909, Mr. Mills was an Assistant Instructor and took a post-graduate course in the University of Michigan, and then, until June, 1910, was Acting Assistant Professor of Civil Engineering in the College of Civil Engineering of Cornell University. In June, 1910, he was appointed Assistant Professor of Materials at Cornell, which position he held in May, 1918, at the time he received his commission as Captain of Engineers, U. S. Army.

From May to December, 1911, he also had responsible charge of the testing of materials used in the construction of Potter's Falls Dam for developing a new water supply for Ithaca, N. Y.

Professor Mills left Ithaca in May, 1918, and was ordered first to Camp Lee, Va. Later, he was transferred to Camp Oglethorpe, Ga., where he remained in training until the latter part of September. He sailed for France on September 29th, and reached there about October 14th, at which time he cabled his family, informing them of his safe arrival. They heard nothing further until November 26th when a message from the War Department announced his death from cerebro-spinal meningitis, in a hospital in Brest, on October 20th, 1918.

* Memoir prepared by E. E. Haskell, M. Am. Soc. C. E.

Professor Mills is survived by his wife and two children, Elizabeth and Adelbert. Mrs. Mills spent the summer of 1918 with her husband at Camp Oglethorpe, and is at present with her parents in Ypsilanti, Mich.

In the death of Professor Mills, Cornell College of Civil Engineering suffers a serious loss. As a teacher, he stood for lofty ideals and thorough work. His own sense of duty was so high, and his scorn for inaction so great, that he was intolerant of laziness and indifference, so that his classes were animated by an intense spirit of energy.

His personal interest in investigation, fortified by his manual skill in devising and constructing apparatus, as well as by his connection with actual problems of engineering practice, gave advanced students in his Department a field of view and a practical interest that proved of great value educationally and reacted in the greater reputation of the College.

In the Faculty, he was invariably a champion of high standards and good work. Impatient of excuses and intolerant of carelessness, he aimed at the establishment of a greater reputation for the College through the better training of its graduates, and though this attitude sometimes savored of harshness, and though students sometimes complained of the rigor of his requirements, he kept always before himself his ideal and refused to compromise with inadequate preparation or inferior ability.

Professor Mills' greatest achievement in scholarship was the production of a thoroughly up-to-date book entitled "Materials of Construction," published in 1915. It has been adopted extensively as a textbook by engineering colleges, and as a standard reference work by engineers in practice. It secured his recognition as an authority on this subject.

Professor Mills was elected a Junior of the American Society of Civil Engineers on September 3d, 1907, and an Associate Member on September 3d, 1913.

JAMES POWELL MURRAY, Assoc. M. Am. Soc. C. E.*

DIED SEPTEMBER 28TH, 1918.

James Powell Murray, son of James W. and Juliette Wingo Murray, was born in Dallas, Tex., on January 18th, 1880. When he was eight years of age his parents removed to Coleman, Tex., where he attended the public schools. He was graduated from the Coleman High School in 1896, and, in 1897, he entered the University of Texas, at Austin, remaining until June, 1901. Mr. Murray returned to the University in 1902, and was graduated with the degree of Bachelor of Science, in June, 1903. Late in the session of 1903-04, he again returned to the University, and did special work throughout that year and at various other times when he had the opportunity, and, finally, was graduated with the degree of Civil Engineer, in June, 1918.

Mr. Murray taught school in Coleman County, Tex., in 1896 and again in 1902. In the summer of 1903 he accepted employment in the United States Geological Survey as an Assistant in a topographic mapping corps in charge of Arthur Alvord Stiles, M. Am. Soc. C. E., Topographer, then engaged in mapping the Chisos Mountains, in Brewster County, Texas. At that time this was a wild section of the Texas-Mexican frontier, known as the "Big Bend" country. The main camp of the topographers was in a canyon in the heart of the mountains, separated from civilization and the railroad by an arid waste of cactus and rocks, a hundred miles or more by any route a man might take. In these solitudes Mr. Murray began his professional career, and learned, from the severe surroundings, the practical things that seem to have served him best in the years that followed. He helped in the geodetic location of Glenn Springs and Boquillas, two places which years later came into National notice over night, when Mexican bandits raided the Big Bend and killed American soldiers guarding the border.

Mr. Murray spent 1905 and 1906 in the Philippine Islands, in the United States Civil Service, as an Assistant Civil Engineer for the Board of Port Works. Returning from the Philippines, he was employed as an Engineer with the Santa Fé Railway on work in Eastern Texas, where he remained until December, 1907. From 1909 to 1913 he was Assistant Engineer of Austin, Tex., and did extensive work in street improvement.

In 1913 Mr. Murray entered the State Reclamation Department of Texas, as Principal Assistant and Civil Engineer, his time being about equally divided between field and office work and service in an advisory capacity. He ran many miles of geodetic traversing and primary leveling, the results of which are published in *Bulletin No. 7* of the State Reclamation Department. He made hydraulic surveys, examined the

* Memoir prepared by Arthur A. Stiles, M. Am. Soc. C. E.

engineering plans of levee districts, and frequently represented the State Reclamation Engineers in matters coming before the Courts. He made the computations for *Bulletins Nos. 5, 5A, and 6,* of the State Reclamation Department, and was joint author of *Bulletin No. 8* of the same Department, entitled "Factors for the Interconversion of Latitudes and Departures, in Feet, and Differences of Latitude and Longitude, in Seconds, 1918."

On June 27th, 1918, Mr. Murray entered the service of the United States as a Captain of Engineers, and went to Camp Lee, Va., for training. While there his company was transferred to Camp A. A. Humphreys, where he completed his course of study. On September 12th, he was ordered to report for duty to the Chief of Engineers at Washington, D. C. He was then ordered to his home in Austin on furlough and to await further orders. At the training camp or *en route* home he contracted Spanish influenza which rapidly developed into pneumonia, and, about four days after arriving at his home, he died. He was buried in Oakwood Cemetery, Austin, with military honors extended by the officers and men of Camp Mabry.

Capt. Murray was married to Miss Alberta Blackburn at Austin, Tex., on April 29th, 1907. His wife and a son, Edward Stuart Murray, survive him.

He was a man of high ideals, a competent civil engineer, and a cultured gentleman, esteemed by the public, and trusted and beloved by his associates.

Capt. Murray was elected an Associate Member of the American Society of Civil Engineers on November 28th, 1916.

ALLEN EUGENE NICHOLS, Assoc. M. Am. Soc. C. E.*

DIED MAY 8TH, 1919.

Allen Eugene Nichols, the son of Eugene M. and Ellen M. Nichols, was born at Madison, Wis., on September 30th, 1888. When he was six years old, his parents moved to Philadelphia, Pa., his father being engaged in the engineering and contracting business. His education, however, was obtained mostly in the West.

In 1906, he entered the Civil Engineering Department of Purdue University, Lafayette, Ind., from which he was graduated in 1910. In 1913, he received the degree of Civil Engineer from the same institution.

On his graduation from college, Mr. Nichols entered the employ of the Baltimore and Ohio Railroad Company, with which company he remained until December, 1910, when he resigned to go with R. L. Sackett, M. Am. Soc. C. E., Consulting Engineer for the State of Indiana, as Assistant in the design of water-works and sewage disposal plants. From April, 1911, to May, 1912, Mr. Nichols was employed by the Chicago and Western Indiana Railroad Company as Assistant Engineer on track elevation and maintenance work. From May, 1912, to February, 1914, he was associated with Alvord and Burdick, Consulting Engineers, as Assistant Engineer on the design and construction of sewage disposal and water supply plants.

From February, 1914, to May, 1915, Mr. Nichols was a student at the University of Pennsylvania, where he made a special study of the chemistry of water. From May, 1915, to January, 1918, he was employed as Engineer in direct charge of the design, specifications and contracts for the Bureau of Waste Disposal of the City of Chicago, Ill. During this time, Mr. Nichols made reports for the Department of Public Works on the mechanical and chemical character of garbage tankage produced by the various cities of the United States, and established a comparison with the standard requirements of the fertilizer trade. He also took charge of the design and specifications for the water purification plant of Oshkosh, Wis.

When the United States entered the World War, Mr. Nichols endeavored to enlist in the Army, but owing to a permanent injury, he was not accepted by the military authorities. He, however, entered the employ of the Du Pont Engineering Company, as Engineer of Construction for a 70 000 000-gal. water filtration plant for the Government powder factory at Old Hickory Works, Nashville, Tenn., which position he retained until construction was completed.

On February 1st, 1919, Mr. Nichols, with his father and brother, entered into a general engineering and contracting business. For many years previous he had given special study to the subject of the disposal

* Memoir prepared by T. McLean Jasper, Assoc. M. Am. Soc. C. E.

of sewage and municipal waste and the utilization and reduction of garbage.

"Nick", as he was called by his immediate friends, was one of those quiet, solid fellows, retiring to the casual individual, but to those to whom he gave his friendship, there was no reserve. Those who had enjoyed that friendship miss the man he was and appreciate the richness of the qualities he had shared among them in the relatively short life he lived.

Mr. Nichols died at his home in Chicago, Ill., on May 8th, 1919, after a short illness, of pneumonia, a transfusion of blood to a near relative a few months before his death, having left him with less than normal vitality to fight the disease.

Mr. Nichols was an Associate Member of the American Society of Mechanical Engineers, a Member of the Franklin Institute, and a Member of the American Water-Works Association and the Sons of the American Revolution.

Mr. Nichols was elected an Associate Member of the American Society of Civil Engineers on October 10th, 1916.

WILLIAM ARTHUR O'BRIEN, Assoc. M. Am. Soc. C. E.*

DIED OCTOBER 12TH, 1918.

William Arthur O'Brien, a son of Judge E. J. O'Brien, prominent in the legal life of St. Louis, Mo., was born in that city on October 5th, 1886. After acquiring a common school education, he entered Christian Brothers College, from which he was graduated in the Engineering Course.

He was usefully employed during his vacations, and following his graduation, he entered the service of the Merchants Bridge Terminal Railroad Company as a Rodman. In August, 1905, he was engaged as Instrumentman with the Chicago, Peoria and St. Louis Railway, and remained with that road until November 1st, 1906, when he was appointed an Assistant Instructor in Railroad Engineering at Purdue University, where, at the same time, he took a special course in mathematics.

In the early part of 1908 Mr. O'Brien was employed as Assistant Engineer for the Little River Drainage District, with headquarters in Cape Girardeau, Mo., and at once became an active participant in the planning of this, the largest drainage district actually undertaken in America, containing about 1 000 sq. miles. On December 1st, 1909, he returned to the Chicago, Peoria and St. Louis Railway, as Engineer of Maintenance of Way, in complete charge of the track and the Bridge and Building Department. There he found a field in which his executive ability manifested itself.

In 1910 the Chief Engineer of the Little River Drainage District, Mr. Otto Kochtitzky, resigned, and the position was tendered to Mr. O'Brien. He accepted it and, on December 1st, 1910, entered upon the performance of the onerous duties connected with that position, discharging them with marked ability. His work there called attention to him, and caused him to receive attractive offers of employment, all of which he declined.

Mr. O'Brien served as a member of the Board of Engineers who prepared to give expert testimony in connection with the litigation arising out of the filing of the plan for the Miami Conservancy District. He was the youngest member of that Board of distinguished engineers.

His powers of analysis were remarkable, and he was so well grounded in mathematics that his knowledge was readily at his command.

In 1912 Mr. O'Brien was married to Miss Amee Conkling, of a prominent family of Springfield, Ill. She survives him, and mourns a very devoted husband.

* Memoir prepared by the late Isham Randolph, M. Am. Soc. C. E.

Naturally high-strung and forceful, he kept his impulses under control and developed a judicial temperament, in which justice moulded firmness. Thus he was in life's business. In life's friendships he was true and generous, and those who were associated with him loved him for all the admirable traits they recognized in him.

Mr. O'Brien was elected an Associate Member of the American Society of Civil Engineers on January 2d, 1912.

HAROLD COE OGDEN, Assoc. M. Am. Soc. C. E.*

DIED OCTOBER 22D, 1918.

Harold Coe Ogden was born in Buena Vista, Colo., on June 12th, 1886. After two years' study in the University of Colorado, he entered active engineering work in 1906. For three years he was engaged principally in mining work in Nevada. From 1909 to 1913 he was with the Arkansas Valley Sugar Beet and Irrigated Land Company at Holly, Colo., on hydrographic work, surveys, and construction.

Coupled with his engineering qualifications, which were of a high character, Mr. Ogden possessed unusual business ability, with the faculty of applying his engineering knowledge of methods and efficiency to practical business problems. He entered commercial life in 1913 as Assistant Manager of the Seattle plant of the Pacific Coast Biscuit Company. He was unqualifiedly successful in his business career, and, at the time of his death, was President and Treasurer of the Seattle Baking Company, which is the largest concern of its kind in Seattle. He was also State Chairman of the Bakers' Service Commission.

Mr. Ogden possessed a pleasing and genial personality which made and held for him a wide circle of friends who are deeply grieved over his early going.

Although for the past few years Mr. Ogden had not been in the active practice of his profession, he continued to have a lively interest in engineering matters, and looked forward to the time when he would resume his engineering activities.

The epidemic of influenza was responsible for Mr. Ogden's death, in Seattle, Wash., on October 22d, 1918. He is survived by a widow and three daughters.

Mr. Ogden was elected an Associate Member of the American Society of Civil Engineers on October 29th, 1912.

* Memoir prepared by S. G. Porter, M. Am. Soc. C. E.

EDWIN JAMES POTTER, Assoc. M. Am. Soc. C. E.*

DIED OCTOBER 18TH, 1918.

Edwin James Potter, the son of Charles F. and Lenora E. (Sayles) Potter, was born in Bridgeton, R. I., on March 17th, 1884. He attended the graded schools of Burrillville, R. I., and was graduated from the Moses Brown School, of Providence, R. I. He took the civil engineering course at Brown University, and received the degree of Bachelor of Science in Civil Engineering in 1907.

During the summer of 1906, Mr. Potter was an Assistant in the office of the City Engineer of Providence, and in June and July, 1907, he was engaged on surveys and drawings for a mile of Macadam road for Burrillville.

In August, 1907, he entered the employ of the B. F. Smith Construction Company, Mill Builders and General Contractors, of Pawtucket, R. I., and for several years thereafter was engaged in estimating, drafting, laying out, and superintending the construction of mills, power plants, storehouses, etc., in New England and New York State.

Mr. Potter's interest in matters relating to engineering was keen, and he lost no opportunity to increase his knowledge of his profession. With this object, he visited the Canal Zone, in order to inspect the Panama Canal before its completion, as well as many other engineering works.

In October, 1913, he took charge of the Hopkins Machine Works, in Bridgeton, and, under his management, the company prospered and increased its business. This concern had been owned by Mr. Potter's family for generations. It was founded by Augustus Hopkins, his great-grandfather in 1836, and from him it went to Mr. Potter's great-uncle, Horatio Hopkins. His grandfather, James Potter, was connected with the company, and his father, also.

Mr. Potter took a keen interest in everything that would be beneficial to the town, and could be relied on to lend a helping hand in any movement for its betterment.

He was a member and Secretary of Pascoag Hose Company No. 2, Past-President of the Alumni Association of the Burrillville High School and of the Moses Brown Alumni Association, and a member of Sigma Chi of Brown University. In all patriotic affairs in this district, he was an active worker, having served as a member of the Liberty Loan Committee and as Chairman of the Burrillville Committee in the War Savings Stamps drive.

* Memoir prepared from information on file at the Headquarters of the Society.

Mr. Potter was a Republican, but did not take an active part in political affairs until 1918, when, after considerable urging, he consented to accept the nomination for State Senator.

He was very much interested in the welfare of the Free Baptist Church, of Pascoag, R. I., and, although he had never united with the church, he had contributed liberally toward its support.

He contracted influenza and died, after a two weeks' illness, at the home of his parents. His death was a shock to the community in which his life had been spent, and a distinct loss to the town. Besides his parents, he is survived by a sister, Mrs. Charles L. Osler, of Malden, Mass., who, shortly after her brother's death, moved to Bridgeton, R. I.

Mr. Potter was elected a Junior of the American Society of Civil Engineers on October 1st, 1907, and an Associate Member on October 1st, 1913.

CAREY SIMON PRATT, Assoc. M. Am. Soc. C. E.*

DIED NOVEMBER 25TH, 1918.

Carey Simon Pratt was born in Quincy, Ohio, on July 7th, 1868. Some time during his young manhood he decided to become a Civil Engineer and make that Profession his life work. Accordingly, from 1888 to 1891, he acquired his technical training in the Ohio State University. Almost immediately after finishing his college course he began serving the public in an official capacity as Deputy County Surveyor in Noble County, Indiana, and continued for the greater part of his life in the public service, although for certain periods he engaged in private work as a Civil Engineer.

From 1893 until 1895, Mr. Pratt served as City Engineer of Sidney, Ohio, and for three years thereafter engaged in private practice as an Engineering Contractor, later, becoming Resident Engineer for the Dayton-Springfield and Urbana Railway. From 1900 to 1902 he occupied the position of Chief Engineer of the Springfield-Xenia Electric Railroad, and, at the same time, acted as Consulting Engineer for the Western Ohio Electric Railroad. It is obvious that he was particularly active during these few years in the development, organization, and maintenance of some of the most important electric railway enterprises in that section of the country and at a time when the electric railroad was being developed at a rapid rate. Men of initiative, ingenuity, training, and ability were just as much required in those days as they were in the early history of steam railroading, and it can be truthfully said that Mr. Pratt possessed all these characteristics in a marked degree.

In 1902, he again returned to public life as City Engineer of Urbana, Ohio, and continued in that position for about eleven years. While serving in this capacity, he designed the sanitary sewer system of Urbana, embracing some fourteen miles of sewers. He also acted as County Engineer of Champaign County, Ohio, from 1902 to 1909, specializing particularly on the design and construction of highway bridges.

From 1913 to 1916 Mr. Pratt was engaged in county bridge work at Sandusky, Ohio, and was also associated with Smith and Boulay of Toledo, Ohio, Consulting Engineers, at both of which places his wide training and the experience gained in his municipal work were of the utmost advantage.

During 1916 and 1917, he supervised one of the first pieces of brick highway construction in West Virginia, just outside of Morgantown. On the completion of that project he came east in the spring of 1917

* Memoir prepared by Harry F. Harris, Assoc. M. Am. Soc. C. E.

and entered the employ of Mercer County, New Jersey, in the capacity of Bridge Engineer. He obtained the appointment to this position through a competitive examination held by the New Jersey State Civil Service Commission, having attained the highest rating of all the competitors for that position. It will be noted that his very decided liking for municipal and public work again asserted itself. Mr. Pratt served as Bridge Engineer until his untimely death.

He was always an intensive student. In fact, it can be said that his real studies did not begin until after he left college. The acquirement of technical knowledge in all the branches of engineering with which he had been connected was one of his greatest hobbies. For years he made a practice of collecting all articles describing any unusual, noteworthy, or ingenious methods for carrying out difficult construction problems, formulas, and new developments pertaining either to the technical or practical side of bridge and highway construction, and as a result of his activities in this direction he had accumulated a rather interesting collection of data and engineering literature which he greatly prized. It was this intense and constant study with so little relaxation that hastened his death.

It is indeed unfortunate that the lives of so many men should be taken just at a period when their age and experience should render them of the utmost usefulness to those they serve, and this means not only the community and mankind generally, but also their families and friends as well. Such was the case when Carey Simon Pratt died on November 25th, 1918.

In 1891 Mr. Pratt was married to Ada Belle Rogers, of Columbus, Ohio. As a result of this union three children—Mrs. Harold Houston, Helen and Lindsay Pratt—were born.

Mr. Pratt was connected with the Masonic Fraternity, in which he took a deep and ardent interest. He was a member of Champaign Lodge, Free and Accepted Masons, of Urbana, Ohio, and also a Knight Templar, belonging to Rapier Commandery of the same city. He was also a member of the American Society for the Advancement of Science.

Mr. Pratt was elected an Associate Member of the American Society of Civil Engineers on June 4th, 1913.

WARD HALL REAM, Assoc. M. Am. Soc. C. E.*

DIED OCTOBER 4TH, 1918.

Ward Hall Ream, son of Mr. and Mrs. J. J. Ream, was born in Oshkosh, Wis., on October 15th, 1886. He attended the public schools of that city, and was graduated from its High School in 1905. In the fall of that year he entered the Webb Academy of Marine Engineering and Naval Architecture, in New York City, from which he was graduated in June, 1908, and then took a post-graduate course at Columbia University in advanced bridge designing and reinforced concrete.

His first work was with the American Bridge Company. He then served as Bridge Draftsman with the Public Service Commission. In 1910 he entered the employ of the Delaware, Lackawanna and Western Railroad Company as Designer and Estimator of Bridges and Stations. His work included the design of railroad and highway bridges, trestles, towers, and various other forms of construction. It was during this period that the railroad did such a large quantity of improvement work, and, with the study of its problems in steel construction, Mr. Ream was intimately connected. He always took especial pride in his work in connection with the construction of the Martin's Creek and Tunkhannock Viaducts on the Clark Summit-Halstead Cut-Off.

In 1915, Mr. Ream joined Company C of the 22d Regiment of Engineers, N. G. N. Y., under the command of Col. Vanderbilt, and, in the summer of 1916, went with his Company to the Mexican border. On his return he proceeded with his work on the Delaware, Lackawanna and Western Railroad improvements, until the United States entered the World War. He then entered the Officers' Training School at Camp Myers, Va., and was awarded a Captain's commission. On account of his age, he would not be allowed to take command in active service, and he thereupon asked for a rerating to First Lieutenant. This was granted, and he was assigned to Company C, 305th Engineers. He went overseas in May, 1918.

On October 2d he took charge of his company, relieving Capt. Matthew J. Hoff, and his recommendation for promotion to a captaincy was forwarded to headquarters. In the early morning of October 4th, his company was ordered forward to assist the infantry in an attack. Lieut. Ream had his company in place, and was just finishing his round of inspection to see that everything was all right, when a high explosive shell struck near him. A fragment hit him in the back of the neck, killing him instantly. He was buried, with military honors, in a little concrete vault which was constructed near the spot where he fell.

His admirable qualities made him popular, not only with his intimate friends, but with all those with whom he came in contact in a business

* Memoir prepared by Edward W. Wendell, Assoc. M. Am. Soc. C. E.

and military way. He was terse, modest, persevering, and courageous, and possessed that other indefinable attrib te which carries with its possessor the ability to see through the veneer of pretence into the heart of the real. He was a most lovable and loyal friend, and his friends mourn his departure, but rejoice in the fact that when his Maker called, he went with the highest honor that a soldier can attain: "Killed in Action."

Besides his parents, he is survived by a sister, Miss Vinnie Ream, of Oshkosh, and one brother, Edward L. Ream, of St. Paul, Minn.

Mr. Ream was elected an Associate Member of the American Society of Civil Engineers on April 18th, 1916.

ALEXANDER CHARLES SCHILLING, Assoc. M. Am. Soc. C. E.*

DIED FEBRUARY 4TH, 1919.

Alexander Charles Schilling was born at New York City, on October 20th, 1886. He acquired his early education in, and was graduated from, the public schools of that city. Later, he received private instruction, and also studied at the Morris High School and the College of the City of New York.

From October, 1904, to July, 1917, with the exception of a short period (October, 1905, to February, 1906), when he was engaged as Transitman with the Rapid Transit Railroad Commission of New York City, Mr. Schilling was employed in the office of the President of the Borough of the Bronx, New York City. In this position, he was engaged chiefly in the construction of sewers and roads.

In July, 1917, he was appointed Assistant Engineer, and, later, Chief of Sewers, United States War Department, and, in this capacity, he designed and constructed sewage works, including septic tanks and disposal plants, located and constructed buildings, theatre, barracks, etc., and supervised the construction of concrete roads, water supply, etc., at Camp Meade, Md.

Of Mr. Schilling's work at Camp Meade, Leo Hudson, Assoc. M. Am. Soc. C. E., who was associated with him there, writes:

"Mr. Schilling came to Camp Meade, Md., from New York City, and proved to be a tireless worker and a man of great worth. He was ambitious and strove continually to improve his own condition and the conditions of those with whom he was associated. His coming to Camp Meade was a personal and professional sacrifice, brought about through a high sense of patriotic duty to help his country in its time of need. He did important work while at Camp Meade, and was there practically from the beginning to the ending of the work. He left behind a good record and a spirit of good fellowship. He left Camp Meade to undertake other work for the Government, which work paid salaries less than those he could have secured from his former employers. He was a splendid young man, and his death is a loss to both the country and the Profession."

On December 19th, 1917, Mr. Schilling was appointed Field Assistant with the U. S. Geological Survey, and had charge of a party controlling areas for topographic mapping. Later, he was detailed in connection with military mapping and served in this capacity until he left the service, on January 15th, 1919.

Mr. Schilling was taken ill while on his way to Mobile, Ala., where he had accepted a position in the U. S. District Engineer's Office. He

* Memoir prepared from information on file at the Headquarters of the Society.

died in Mobile, on February 4th, 1919, from influenza, followed by broncho-pneumonia. His death came as a great shock to his family and to all his associates.

He was married on September 24th, 1910, to Miss Grace Mattock Willey, of New York City, who, with two children, Alexander Ralph and Grace Marjorie, survives him.

Mr. Schilling had a keen appreciation of Nature, and was a lover of outdoor life. His boyhood days were spent largely in the woods, and he was greatly interested in ornithology, having had, at one time, a large collection of live birds. He was a vigorous young man, and no amount of work phased him. All his leisure time, and most of his working hours, were spent in the open. Several years ago, he was the possessor of an auxiliary sloop yacht, and his knowledge of the channels, together with his excellent eyesight, made him a capable captain. He had explored the country by motorcycle and automobile, and was extremely fond of travel, quoting many, many times:

> "To him who in the love of Nature holds
> Communion with her visible forms, she speaks
> A various language;"

Mr. Schilling was elected an Associate Member of the American Society of Civil Engineers on June 18th, 1918.

GEORGE CORLISS SEE, Assoc. M. Am. Soc. C. E.*

DIED AUGUST 28TH, 1918.

George Corliss See, son of James W. and Hester Rose See, was born in Hamilton, Ohio, on June 25th, 1882. He received his preliminary education in the public schools of Hamilton, and was graduated from the Rensselaer Polytechnic Institute in 1905, with the degree of Civil Engineer.

Early in life Mr. See evinced an aptitude for the profession he was to follow. In 1900 he entered the office of his father, Mr. J. W. See, Consulting Engineer, in the capacity of a Draftsman and Designer. Prior to entering the Rensselaer Polytechnic Institute, he was employed as a Rodman by the United States Engineer Department, in Havana, Cuba. Upon graduation Mr. See was employed by the Manhattan Trap Rock Company, at Nyack, N. Y., as Assistant Superintendent, until October, 1905, when he entered the employ of the New York and Long Island Railroad Company. His thorough and painstaking work while connected with the latter company earned for him rapid promotion. In 1906 he had risen from the grade of Rodman to that of Chief of Party. In this capacity Mr. See had charge of the grade and alignment of the Manhattan end of the Belmont Tunnels.

In October, 1906, he became Assistant Engineer of the Fonda, Johnstown and Gloversville Railroad Company. In addition to the duties of general maintenance-of-way work of the road, Mr. See supervised the construction of a four-arch concrete bridge for a grade crossing elimination. He also designed and supervised the construction of many other improvements undertaken by the company during his two years stay with this road.

The last ten years of Mr. See's life were spent in highway work. He was Assistant Engineer and Assistant to the Division Engineer, New York State Highway Department, with headquarters in Albany, from March, 1908, to August, 1917. After his first few years in this service, Mr. See became recognized as one of the foremost highway engineers in his Department. He was entrusted with the supervision of all highway construction in five counties of the Division. In May, 1914, he secured a leave of absence from the State Department of Highways, and, forming a partnership with Harrison Smith, Assoc. M. Am. Soc. C. E., opened an office in Temple, Tex., for the practice of highway engineering. The firm did an extensive business, and it was due to failing health that Mr. See relinquished the field and returned to his former duties in Albany.

In August, 1917, Mr. See was appointed Senior Highway Engineer for the United States Department of Public Roads, with headquarters

* Memoir prepared by J. C. Watts, Engr., Harbor and Dock Comm., Troy, N. Y.

in Montgomery, Ala. A few weeks prior to his death, he had received orders for transfer from Montgomery to Washington, D. C. While spending a short vacation in Troy, N. Y., before proceeding to his headquarters, he was taken ill, and died the second day following.

Besides his wife and son, Mr. See is survived by a host of friends. His genial nature made him loved by all who knew him. His careful, efficient, and painstaking manner made him always a valuable asset to whatever corporation he served. His brilliant and scholarly attainments have made for him a record well worthy of his profession.

Mr. See was a member of Sigma Xi fraternity and of the Rensselaer Society of Engineers. He was elected a Junior of the American Society of Civil Engineers on September 3d, 1907, and an Associate Member on September 2d, 1914.

ROBERT EARLE SHIPLEY, Assoc. M. Am. Soc. C. E.*

DIED OCTOBER 11TH, 1918.

Robert Earle Shipley, the son of Dr. John L. and Mary E. Shipley, was born on December 30th, 1887, at Cullychoha, Indian Territory. His parents died when he was a small boy, and he made his home with his aunt, Mrs. Sarah McConnell. After finishing the public schools, he entered the High School in his home town, and, later, the University of Arkansas, from which he was graduated with the degree of B. C. E., in June, 1911. He was a member of the Phi Kappa Alpha Fraternity.

Mr. Shipley's professional career was as follows: March to August, 1909, Field Draftsman, with the Arkansas Co-operative Constructing Company, Bentonville, Ark., on preliminary and location surveys; July to December, 1911, Inspector of levees and dredge ditches, St. Francis Drainage District; December, 1911, to April, 1912, Draftsman on drainage surveys; April, 1912, to June, 1913, Engineer and Assistant Superintendent for A. B. Wills and Sons, Drainage Contractors, on the inspection of drainage districts, making estimates, designing dredge boats, etc.; June to November, 1913, Field Engineer for James R. Rhyne, Assoc. M. Am. Soc. C. E., in charge of the preliminary survey for a 30 000-acre drainage district; November, 1913, to September, 1914, Resident Engineer for the Marion County Drainage District, supervising the construction of levees, open and title ditches, as well as the erection of a pumping station and the installation of two 30 000 gal. per min., electrically-driven centrifugal pumps; February to September, 1914, also Chief of a field party on a levee and ditch location survey for the South Quinch Drainage District; October, 1914, office work with the Morgan Engineering Company; November, 1914, to November, 1915, made a drainage survey and reported on 300-acre farm and drainage and irrigation investigations in the Southwest; from November, 1915, to the summer of 1918, when he entered the military training camp, Mr. Shipley was employed as Drainage Engineer, for the Texarkana Pipe Works, making drainage surveys, designs, estimates, and reports, closing contracts and superintending all the drainage construction work for the Company.

He entered the First Engineer Officers' Training School, at Camp A. A. Humphreys, Va., in June, 1918, where he died of influenza on October 11th, 1918.

He was married to Miss Helen Cook, of Texarkana, Ark., on June 27th, 1918, and is survived by his wife, and two brothers, Lieut.

* Memoir prepared by J. H. Brillhart, M. Am. Soc. C. E.

John I. Shipley, M. D., U. S. N., and Elvin M. Shipley, who was stationed at Great Lakes, Ill., in the Aviation Service of the United States Navy.

Of Mr. Shipley, L. L. Hidinger, M. Am. Soc. C. E., Vice-President of the Morgan Engineering Company, says, "He was connected with our firm only a short time, but we were impressed with his stability of character, steadiness, and reliability." Mr. G. R. Layne, of the Texarkana Pipe Works, writes of him as follows: "My acquaintance with Mr. Shipley dates from the time he entered my employ about four years ago. He was with us three years as Drainage Engineer, principally on agricultural work, and I esteemed him very highly, not only for the value of his services, but as a thorough gentleman."

Mr. Shipley was a man of high moral character, modest and unassuming. Owing to the fact that his father died when he was still young, he was thrown on his own resources, and the record that he made in his short life, shows that he was efficient and thorough, and that the Profession lost a valuable man by his death.

Mr. Shipley was elected an Associate Member of the American Society of Civil Engineers on October 9th, 1917.

EDGAR FIELD SMITH, Assoc. M. Am. Soc. C. E.*

DIED OCTOBER 17TH, 1918.

Edgar Field Smith, the son of the late Ransom Eugene and Anna Lydia (Grout) Smith, was born at Saxtons River, Vt., on December 25th, 1877. He received his early education in the public schools of his home town, and in Vermont Academy, and was graduated from Boston University in 1900 with the degree of A. B.

After his graduation Mr. Smith worked as a Draftsman for a few years with several firms about Boston, among which were the Century Machine Company, the John Stuart Company, of Wollaston, Mass., and Sheaf and Jaastad, Electrical Engineers, of Boston.

In September, 1902, he entered the Massachusetts Institute of Technology, and was graduated in June, 1904, with a degree of B. S. in Civil Engineering.

From June to October, 1903, he was an Assistant Engineer with H. S. Ferguson, M. Am. Soc. C. E., at Millinocket, Me., and from June to September, 1904, he served as a Transitman for the Boston Elevated Railway Company. From September, 1904, to June, 1905, Mr. Smith was employed by the United States Government at Parkersburg, W. Va., on the construction of Lock and Dam No. 18, Ohio River. In June, 1905, he became Designing Draftsman for the Bureau of Filtration, Pittsburgh, Pa.

Late in 1905 he left Pittsburgh to accept a position in New York City with the New York Central Railroad. Early in 1906 he was appointed Assistant Engineer in the Construction Department of the International Paper Company, of New York City.

In September, 1907, Mr. Smith became an Assistant Engineer and Designer with the New York Board of Water Supply, with which he remained up to the time of his death on October 17th, 1918, except for a period of ten months, from September, 1911, to July, 1912, when he was Assistant Professor of Civil Engineering at the Brooklyn Polytechnic Institute. With the Board of Water Supply he advanced to the position of Assistant Designing Engineer in charge of a squad, and had responsible charge of designing portions of the steel pipe siphons of the Catskill Aqueduct, of the connection chambers of the City Aqueduct Pressure Tunnel, of the City pipe lines, of the Narrows Crossing, and of the Eastview Filters.

In addition to his work with the Board of Water Supply, he was an Instructor in Surveying at the Brooklyn Polytechnic Institute for the extension classes from 1907 to 1918, and at the time of his death was about to take a similar position at Cooper Union.

* Memoir prepared by Arthur R. Holbrook, Assoc. M. Am. Soc. C. E.

Mr. Smith's work was marked by thoroughness, neatness, and system; he believed in doing well everything he undertook; he was very accurate, and possessed an excellent memory.

He was married on September 12th, 1907, to Miss Caroline Leicht, of Southold, Long Island. He is survived by his widow and one child, Edgar Field, Jr., two brothers, Walter Leroy Smith and R. Eugene Smith, of Malden, Mass., and one sister, Mrs. Della (Smith) Brett of Miami, Fla. He was very much devoted to his family.

Mr. Smith's death was very sudden; he fell a victim to the epidemic of influenza, followed by pneumonia, which swept this country in the latter part of 1918.

He was a member of the New England Water Works Association, and of the Beta Theta Pi Fraternity, which he joined while at Boston University.

Mr. Smith was elected an Associate Member of the American Society of Civil Engineers on May 1st, 1907.

AUSTIN RUSSELL WILLARD SPERRY, Assoc. M. Am. Soc. C. E.*

DIED DECEMBER 6TH, 1918.

Austin Russell Willard Sperry, the only son of Austin B. and Katherine M. Sperry, of the family that organized the Sperry Flour Company, was born in Stockton, Cal., on December 26th, 1888.

He attended the Stockton schools, spent two years in the High School, and then went to Berkeley and studied at Boone's University School for two years. He was graduated in Civil Engineering from the University of California in 1910, having been a member of the G. E. K. High School Fraternity and the Alpha Delta Phi College Fraternity. He was a member of the 'Varsity crew and was also an accomplished 'cellist.

Immediately after his graduation, Mr. Sperry started work as an Inspector in the Maricopa oil fields, but soon moved to the Crocker-Huffman Irrigation Project, near Merced, and before the completion of this work he had risen to be Chief Engineer. He continued this specialty of irrigation engineering until his death. In 1912, he took hold of an irrigation unit for the Natomas Company of California and completed an extensive system. He then directed the operation and maintenance of the system, and also took charge of the works of the Folsom Water Company, looking after the water supply and retaining dams in connection with the fleet of gold dredges operated by this Company.

In March, 1917, he accepted the position of Supervising Engineer for the Anderson Cottonwood Irrigation District, in the Upper Sacramento Valley, and directed work involving an expenditure of $700 000. The many extensive and, in several cases, unique structures in this District, as well as the excellent character of the work, stand as monuments to Mr. Sperry's engineering ability and initiative.

In addition to his engineering activities, Mr. Sperry was associated in a financial way with the Rising River Ranch Company, which owns extensive stock ranges.

On September 25th, 1912, he was married to Gertrude Fancher, of Merced, Cal., who died on January 19th, 1917, leaving one daughter, Katherine. On July 12th, 1918, he was married to Marguerite Cron, of Berkeley, Cal., who, with his mother, survives him.

His integrity of character, lovable personality, and ability in handling men had endeared him to all with whom he came in contact, and the blow to his loved ones and friends was the more severe in that he

* Memoir prepared by R. G. Clifford, Assoc. M. Am. Soc. C. E.

was stricken suddenly, in the prime of life, with a brilliant future opening up in his chosen profession. He leaves a host of warm personal friends and business associates.

Mr. Sperry was elected a Junior of the American Society of Civil Engineers on December 6th, 1910, and an Associate Member on January 15th, 1917.

GEORGE HIPPESLEY STANLEY STEPHENS, Assoc. M. Am. Soc. C. E.*

DIED OCTOBER 13TH, 1918.

George Hippesley Stanley Stephens, the eldest son of Frederick Orlando Stephens, now of The Homestead, Orangezicht, Cape Town, South Africa, was born in Norwich, England, on November 20th, 1882. He was educated at Tunbridge Wells, England, and at the Diocesan College, South Africa. He was articled to his father, a Civil Engineer, from 1900 to 1905.

From 1901 to 1908, Mr. Stephens was engaged as Field Assistant and Assistant Engineer by Messrs. G. Pauling and Company, Limited, of London and Cape Town, on the surveys and construction work in connection with the extension of the New Cape Central Railway to Mossel Bay, in Cape Colony, South Africa, and the Stuartstown Railway in Natal. In 1908 and 1909, he was employed by the same firm as Assistant Engineer on the survey of the Bwana Mkubwa ("Star of Congo") Railway, from the Bwana Mkubwa copper mine, in Northwestern Rhodesia, to the "Star of the Congo" Mine, in the Congo State.

In 1909 and 1910, Mr. Stephens served as Assistant Engineer on the construction of the Bwana Mkubwa and Broken Hill Railway, in Northwestern Rhodesia, and from that time until the early part of 1911, he was engaged as First Assistant Engineer on the survey of the Mazoe Railway, also in Rhodesia.

From 1911 to 1917, he was employed by the South African Railway Administration on the construction of the railway extension from Caledon, Upington, and Carnarvon, and, from that time until his death which occurred at Paarl, South Africa, on October 13th, 1918, Mr. Stephens was engaged on various surveys and investigations for irrigation projects for the Department of Irrigation in the Union of South Africa.

Mr. Stephens' untimely death, from pneumonia supervening influenza, at the age of 36, came as a painful shock to his professional associates and to his wide circle of friends in many parts of Southern Africa. To all of them he was the soul of friendship, and there must still be many who, in the course of the lonely journey by which entry to the Congo from the south was made before the construction of the railway was completed, can recollect his warm welcome and generous hospitality on their way through the illimitable veldt. His largeness of heart indeed was his chief characteristic, and, with it, there went a cheerfulness and constancy that braved every trial, shining even more brightly when the final command came for him, too, to "pass over".

* Memoir prepared from information on file at the Headquarters of the Society.

The thorough training which Mr. Stephens had enjoyed under all classes of South African conditions, had eminently fitted him for the highest positions in the service to which he was finally attached, and his early death will prove a loss to the Union in which he had made his home.

Mr. Stephens was married in 1916 to Grace Winifred Taylor, the only daughter of Charles Taylor, of Paarl, who survives him after a brave struggle with the epidemic which, in October, 1918, swept through South Africa.

Mr. Stephens was elected an Associate Member of the American Society of Civil Engineers on December 5th, 1911. He was also an Associate Member of the South African Society of Civil Engineers.

EDWARD PORTER ALEXANDER, Jun. Am. Soc. C. E.*

DIED SEPTEMBER 5TH, 1918.

Edward Porter Alexander was born at Duluth, Minn., on November 4th, 1891. He was a lineal descendant of Gen. E. P. Alexander, of Georgia, a graduate of West Point and an officer in the Civil War.

Edward Porter Alexander attended school in Duluth and then entered the University of Minnesota, after which he received his engineering education at the Massachusetts Institute of Technology, from which he was graduated in 1914 with the degree of B. S. in Civil Engineering. He returned to Duluth where he formed a partnership with Mr. James A. Farrell, covering the field of general surveying, municipal, railroad, and mining engineering.

At the beginning of the trouble with Mexico, Mr. Alexander, while still at the Institute of Technology, made application for a commission in the army; and, when the United States entered the World War, he received his commission as First Lieutenant in the Engineers Reserve Corps. He entered the training camp at Fort Snelling, Minn., was afterward transferred to the Engineers Training Camp at Leavenworth, Kans., and from there was sent to Fort Travis, Tex., for overseas training. He was with the 509th Engineers at St. Nazaire, France, as Adjutant, up to the time of his death.

Mr. Alexander was a very capable and energetic man, of high character and pleasing personality. He was married on August 20th, 1917, to Miss Myra Salyards, of Duluth, who survives him.

Mr. Alexander was elected a Junior of the American Society of Civil Engineers on November 4th, 1914.

* Memoir prepared by Lyonel Ayres, M. Am. Soc. C. E.

VICTOR HUGO BELL, Jun. Am. Soc. C. E.*

DIED JANUARY 6TH, 1919.

Victor Hugo Bell was born at Hutchinson, Kans., on July 6th, 1891. When he was only a few years old, his mother moved to San Diego, Cal., where the boy received his early schooling. He began his engineering studies at the University of Washington, and, in 1912, entered Valparaiso University at Valparaiso, Ind., from which he was graduated with the degree of B. C. E. in June, 1914, receiving his C. E. degree in August of the same year. At college, Mr. Bell had the reputation of being an honest, energetic, and apt student.

Prior to entering college, he was employed from March to November, 1910, as Stakeman, Chainman, and Leveler with the Chicago, Milwaukee and Puget Sound Railway Company; and from December, 1911 to March, 1912, and from March to June, 1912, as Transitman with L. B. Harris, Consulting Engineer, of San Diego, Cal., and the Western Salt Company, of Otay, Cal., respectively.

Immediately after his graduation in 1914, Mr. Bell returned to California and opened an office in Calexico for the private practice of engineering. His work there was chiefly in connection with the irrigation of the Imperial Valley, such as erecting timber headgates and bulkheads for the South Alamo Water Company, irrigation, land grading, and the subdivision of 169 acres into city lots, for the Royal Lands Company, as well as assisting the City Engineer of Calexico and working on numerous other engineering and surveying jobs.

When the United States entered the World War, Mr. Bell closed his office in Calexico and enlisted in the Army. He entered the Science and Research Division and was graduated as a Second Lieutenant from the United States Army School in Texas. He was then assigned to the Science and Research Division of the Army Balloon School at Arcadia, Cal., where he was stationed at the time of his death. He was killed on January 6th, 1919, in an automobile accident on the highway between Pasadena and Los Angeles, and was buried with full military honors at Fort Rosecrans, Cal. He is survived by his mother, Mrs. Mary F. Bell.

Lieut. Bell was a Member of the Western Society of Engineers and was prominent as a Knight of Columbus. He was elected a Junior of the American Society of Civil Engineers on March 14th, 1916.

* Memoir prepared from information on file at the Headquarters of the Society.

DEAN CHASE, Jun. Am. Soc. C. E.*

DIED MAY 26TH, 1919.

Dean Chase, the son of Clinton Alden Chase and Sallie Harmon Chase, was born at St. Louis, Mo., on May 5th, 1890. After having been graduated from the McKinley High School, at St. Louis, in 1909, he spent one year in the Engineering Department of the Missouri Pacific Railway. In 1910, he entered the University of Illinois, from which he was graduated in 1914, as a Municipal and Sanitary Engineer, with the degree of B. S.

After his graduation, Mr. Chase entered the employ of the Water Department of the City of St. Louis, and during parts of 1914 and 1915, was engaged at the Chain of Rocks on the construction of the new filtration plant.

On the completion of this work in the spring of 1915, he concluded to enter the commercial field, and secured a position with the Certainteed Products Corporation as Traveling Salesman, with headquarters at New Orleans, La. Mr. Chase was signally successful in his new endeavor and continued at this work until shortly after the declaration of war with Germany, when he entered the First Officers' Training Camp, at Fort Logan H. Roots, near Little Rock, Ark. After he had been there several weeks, he was rejected for trivial physical defects. Although greatly disappointed, he was undaunted in his zeal to go to his country's aid, and in August, 1917, he enlisted again at New Orleans, and soon thereafter entered the Second Officers' Training Camp, at Fort Winfield Scott, Cal.

On November 27th, 1917, Mr. Chase was commissioned a First Lieutenant in the Coast Artillery Corps, and was assigned to the 62d Regiment, with which he was identified until he was honorably discharged from the service at Camp Custer, Mich., on March 8th, 1919. He saw service with his regiment in France from July 31st, 1918, to February 6th, 1919, but did not get to the front, although the regiment was about to be ordered there when the Armistice was signed. On account of his appointment as Regimental Orienteur, Lieut. Chase became a Staff Officer and was twice recommended for promotion, but, here, again, the signing of the Armistice prevented fulfillment. On May 26th, 1919, the evening of which he met his death, he was commissioned First Lieutenant, Coast Artillery Section, Officers' Reserve Corps of the U. S. Army.

From about March 20th, 1919, to the time of his death on May 26th, 1919, Lieut. Chase was in the employ of the Certainteed Products Corporation as traveling representative, with headquarters at Syracuse, N. Y. On the evening of the fateful day, while motoring

* Memoir prepared by C. W. Roehrig, Esq., St. Louis, Mo.

near Utica, N. Y., with two prospective customers, they met with an accident, the machine being overturned, and Lieut. Chase was killed instantly. He was buried from the family residence in St. Louis, Mo., on May 30th, 1919, with military honors.

Lieut. Chase possessed an analytical mind and the power of concentration to a high degree, and this was reflected in his student and professional life. He had a most promising career before him, and his untimely taking away will be mourned by a large circle of friends. He had led an honest, upright, and morally clean life, and was loved and respected by all who knew him.

Lieut. Chase was a Member of the Engineers' Club of St. Louis, and was elected a Junior of the American Society of Civil Engineers, on June 3d, 1915.

ERNEST CHARLES DEDICKE, Jun. Am. Soc. C. E.*

DIED JULY 15TH, 1918.

Ernest Charles Dedicke was born on February 19th, 1889, in the village of Dolgeville, Herkimer County, N. Y. His early childhood days were spent in the place of his birth, and it was here that he received most of his grammar school education. At the age of twelve, he moved with his family to Hamburg, Germany, where he remained until 1905, and where he completed his high school education.

On his return to the United States, the young lad, led by the same adventurous spirit that brought him back to his native shores, and prompted by a rare love of country which had become the more pronounced during his stay on foreign soil, joined the United States Army. He was assigned to the 11th U. S. Cavalry, and, with that regiment, took part in the campaign of Cuban Pacification, in 1906-08. He was honorably discharged in 1908, having reached the grade of Sergeant, which, in the old army, was a rare achievement for one of his years.

Mr. Dedicke returned to the States and took up the study of expert accountancy at Valparaiso University. While employed as Assistant at the Remington Works, at Ilion, N. Y., his health failed, and he was compelled to turn to the life of the great outdoors. His choice fell on the Engineering Profession. While gathering practical knowledge, he acted as Foreman on the construction of a large dam at Dallas, Tex., also on another at Hinkley, N. Y., and was connected with several highway improvement contracts in various parts of New York State. Besides thus gaining practical experience, he was diligently studying with the American School of Correspondence. In 1913, Mr. Dedicke was appointed Junior Engineer under the Civil Service System of the City of New York, and was employed on the construction of the New York City Subways. In 1914, he was transferred to the Utica Office of the New York State Highway Department, where he remained until he once more joined the colors. This was at the time of the Mexican trouble.

He enlisted in Troop G, of the 1st New York Cavalry, at Utica, N. Y., with which he saw service on the Mexican border until the early spring of 1917. He then received a commission as Second Lieutenant of Engineers, and was ordered to Madison Barracks, N. Y., for training. Three months later, he was assigned to the 6th U. S. Engineers, at Washington Barracks, D. C., and with that regiment left for France in November, 1917. This outfit did splendid work as an independent unit with the British Army. Company D, of which Lieut. Dedicke was First Lieutenant, was decorated for bravery by the British Government, for heroic work with the now famous emergency army of

* Memoir prepared by O. J. Dempster, M. Am. Soc. C. E.

Gen. Carey, which army held back the German advance in March, 1918, until reinforcements arrived. In April, the 6th Engineers were assigned to the Third Division, and with the Second Division won immortal fame at Chateau Thierry, in June and July, 1918. In July, Lieut. Dedicke was assigned as Engineer Officer with the 4th U. S. Infantry, and as such had charge of all trench work and barbed wire entanglements.

It was while directing the construction of these works, 5 km. east of the now famous French town of Chateau Thierry, and during the early morning German barrage of July 15th, 1918, that Lieut. Dedicke was mortally wounded by shrapnel, dying at 5 o'clock that afternoon, in Field Hospital No. 27.

He was beloved by his men and respected by his superiors, and was a finely trained engineering officer. He is sleeping the eternal sleep among his fellow heroes in Cemetery No. 284, near the spot where the ambitions of the Hun were stayed.

Lieut. Dedicke was elected a Junior of the American Society of Civil Engineers on November 28th, 1916.

DONALD POWER DENHAM, Jun. Am. Soc. C. E.*

DIED OCTOBER 23d, 1918.

Donald Power Denham, the son of Mr. and Mrs. W. H. Denham, was born at Akron, Ohio, on June 14th, 1890. In 1904, the family moved to Peterborough, Ont., Canada, and the boy prepared for college at the Peterborough Collegiate Institute. In 1910, he entered Cornell University, from which he was graduated in 1914 with the degree of Civil Engineer.

In April, 1915, Mr. Denham entered the employ of the Leonard Construction Company, and was engaged on work for that Company, as follows: Until April, 1916, as Field Engineer on the construction of a reinforced concrete ore bin and a reinforced concrete steel mill building for the New Jersey Zinc Company, at Franklin, N. J.; from April to October, 1916, as Resident Engineer on the construction of a garbage plant for the Metropolitan By-Products Company, on Staten Island, New York; and from October to December, 1916, on the construction of a reinforced concrete building for the Douglas Starch Company, at Cedar Rapids, Iowa.

In December, 1916, Mr. Denham's services were loaned by the Leonard Construction Company to the Quaker Oats Company for special drafting and designing in connection with the construction of the latter's plant at Cedar Rapids, Iowa, and from February to May, 1917, he was engaged as Field Engineer on the construction of reinforced concrete buildings for the Sinclair Oil Company, at Kansas City, Mo. Later, he went to Peterborough, Ont., Canada, as Engineer in Charge for the Quaker Oats Company on the construction of its immense plant at that place. He was also engaged at Saskatoon, Sask., Canada, on mill construction for the same Company.

When war was declared, Mr. Denham made repeated efforts to get into military service, but owing to a severe illness a short time before, he was unable to pass the physical examination. While working at Saskatoon, he received a Government appointment with the United States Bureau of Yards and Docks, at Charleston, S. C., and was on his way to that place when he was taken ill with pneumonia from which he died on October 23d, 1918.

While at Cornell Mr. Denham was a member of the Sigma Nu, Semaphore, and Glee Clubs, and he was also a member of the *Civil Engineer* Board.

Mr. Denham was elected a Junior of the American Society of Civil Engineers on April 17th, 1917.

* Memoir prepared from information on file at the Headquarters of the Society.

RALPH RICHARDSON MARRIAN, Jun. Am. Soc. C. E.*

DIED OCTOBER 17TH, 1918.

Ralph Richardson Marrian was born at Watertown, N. Y., on March 24th, 1890. He received his early education in the Watertown schools, and then attended Cornell University, from which he was graduated with the degree of Civil Engineer in 1915.

During the summer of 1914 Mr. Marrian was a Transitman in the Engineering Department of the New York Central Railroad, and, in June, 1915, was employed by Messrs. Hazen, Whipple and Fuller, in New York City. While so engaged, he enlisted in the Seventh New York Infantry, and, in the summer and fall of 1916, served with that regiment on the Mexican border. On the return of the regiment, he was discharged.

When the United States entered the World War, Mr. Marrian re-enlisted and received a commission as Second Lieutenant. After two months of training at Camp American University, in Washington, D. C., he was assigned to the 105th U. S. Engineers, then stationed at Camp Sevier, Greenville, S. C. In May, 1918, he went overseas with that regiment, and soon afterward was promoted to the rank of First Lieutenant.

Lieut. Marrian was wounded on October 17th, 1918, by a bursting shell while repairing roads under shell fire near Molain, northeast of Bohain, in France, in order that artillery might follow up an infantry drive. A shell burst near him and his men, killing two outright and wounding four besides himself. He died soon after he was carried to the main dressing station, and was buried in the Military Cemetery at Montbrehain, where his company built a fence around the grave and placed a cross at its head.

Col. Joseph Hyde Pratt, commanding the 105th Engineers, in reporting his death to his family, wrote that Lieut. Marrian had been doing splendid service, and added: "He was brave, conscientious, and a good leader. He had the confidence of his men, and he and they gave the best they had for their country."

Lieut. Marrian was elected a Junior of the American Society of Civil Engineers on April 18th, 1916.

* Memoir prepared by Woodford Patterson, Esq.

RICHARD JETER PALMER, JR., Jun. Am. Soc. C. E.*

DIED OCTOBER 13TH, 1918.

Richard Jeter Palmer, Jr., was born at Harmony Village, Va., on August 10th, 1887. He finished his course at West Point Academy in the spring of 1903, and, in the fall of that year, entered Washington and Lee University, where he remained until 1905. Then he entered the Virginia Polytechnic Institute, and was graduated in 1907 with the degree of Bachelor of Science.

From August, 1907, until June, 1908, was employed as Draftsman by the American Bridge Company, at Trenton, N. J., and then opened an office at West Point, Va., doing private engineering work and land surveys, sewer and highway construction being a specialty. In November, 1909, he entered the employ of the Gulf, Colorado and Santa Fé Railway. During the 19 months he was in the service of this road he had several promotions. He then accepted a position with the Richmond Cedar Works, as Instrumentman, making land, timber, and drainage surveys.

In April, 1912, Mr. Palmer entered the service of the Norfolk and Western Railroad, as Rodman, and, after 3 months, he was made Inspector on the construction of a twenty-one stall round-house, turntable, machine shop, blacksmith shop, oil house, storehouse, coaling station, 100 000-gal. reinforced concrete tank, ash hoist, and minor auxiliaries. After completing this work he became Instrumentman on maintenance of way, making yard layouts and estimates.

Mr. Palmer was appointed Resident Engineer on the construction of two steamer warehouses, 800 and 1 200 ft. long, respectively, and each 222 ft. wide, the development cost being $1 800 000. During the last 18 months he was on railroad construction at Camp Lee, Va., and the rearrangement of Coal Pier No. 3, at Norfolk, Va.

In his professional career, Mr. Palmer developed those qualities which insure success. Owing to his fine qualities for thoroughness and as a man he won the esteem of all with whom he came in contact.

He was married to Miss Edyth Atwood, of Appomattox, Va., on October 15th, 1912.

On October 2d, 1918, he contracted influenza which developed into pneumonia and caused his death on October 13th. He is survived by his wife, mother, brother, and two sisters.

Mr. Palmer was elected a Junior of the American Society of Civil Engineers on October 10th, 1916.

* Memoir prepared by Loomis L. Kelly, Esq.

CHARLES GILBERT REILLY, Jun. Am. Soc. C. E.*

DIED SEPTEMBER 29TH, 1918.

Charles Gilbert Reilly, the son of the late John C. Reilly and Ursula O'Connor Reilly, was born at Pittsburgh, Pa., on December 12th, 1889. After his preliminary schooling, Mr. Reilly entered Princeton University, from which he was graduated in June, 1912, with the degree of Civil Engineer.

After his graduation, Mr. Reilly traveled in Europe for several months, and, on his return to Pittsburgh, entered the employ of the Pittsburgh Railways Company, on double-track work from Pittsburgh to Castle Shannon, on the Castle Shannon Division. He was also engaged, for a short time, as Engineer with the Philadelphia Company, of Pittsburgh.

In 1915, he was appointed Superintendent of Construction on the plant of the Pittsburgh Model Engine Company, of which company he was also a Director and Assistant to the President.

In May, 1917, one month after war with Germany was declared, Mr. Reilly entered the First Officers' Training Camp at Fort Niagara, N. Y., and was commissioned a First Lieutenant. In August, 1917, he was assigned to Company D of the 313th Infantry, then stationed at Camp Meade, Md., where he remained until he sailed for France with the Seventy-ninth Division in July, 1918. Lieut. Reilly had been in France only one month when he was promoted to be Captain of his company.

With the Seventy-ninth Division, his company saw hard service on the fighting line in France, and Capt. Reilly was killed in action on September 29th, 1918, during the drive in the Argonne Forest.

Capt. Reilly was of an amiable and happy disposition, with a smile for every one, and had made for himself many friends. During his college days, he was Assistant Manager and Manager of the baseball team at Princeton and a member of the Tiger Inn Club. He was also a member of the Pittsburgh Athletic Association and the Oakmont Country Club.

Capt. Reilly was elected a Junior of the American Society of Civil Engineers on May 7th, 1913.

* Memoir prepared from information on file at the Headquarters of the Society.

"Final Report of the Special Committee on Steel Columns and Struts." Lewis D. Rights, James H. Edwards, C. W. Hudson, Charles F. Loweth, Ralph Modjeski, George F. Swain, Emil Swensson, and J. R. Worcester. 1583. Discussion: Henry S. Prichard, Gustav Lindenthal, Charles Evan Fowler, J. A. L. Waddell, Edward Godfrey, William H. Burr, R. von Fabrice, and L. J. Mensch. 1634.

"Second Progress Report of the Special Committee to Report on Stresses in Railroad Track." Arthur N. Talbot, A. S. Baldwin, G. H. Bremner, John Brunner, W. J. Burton, Charles S. Churchill, W. C. Cushing, W. M. Dawley, Robert W. Hunt, J. B. Jenkins, George W. Kittredge, Paul M. LaBach, C. G. E. Larsson, G. J. Ray, Albert F. Reichmann, H. R. Safford, F. E. Turneaure, J. E. Willoughby. 1409. Discussion: A. W. Buel, and E. P. Goodrich. 1581.

RESERVOIRS.

"Construction Methods Used in Building the Lower Reservoir Dam of the Balmorhea Project." Vernon L. Sullivan. (With Discussion.) 305.

"The East Canyon Creek Dam." A. F. Parker. (With Discussion.) 574.

"The Silt Problem of the Zuni Reservoir." H. F. Robinson. 868. Discussion: Elwood Mead, Clarence S. Jarvis, and George M. Post. 879.

RIVERS.

Application of the theory of flow through contractions to the design of the flood-prevention works of the Miami Conservancy District. 1205.

"Physiography of Water-Sheds and Channels, and Analysis of Stream Action of Southern California — , with Reference to the Problems of Flood Control." A. L. Sonderegger. 1111. Discussion: Charles A. Pohl, Francis H. Wright, H. F. Dunham, and Fred D. Bowlus. 1135.

ROADS.

See **HIGHWAYS.**

ROLLING STOCK.

— on light railways in France. 1220.

Tests to determine the effect of speed and counterbalance on stresses in rail. 1414.

SAND BLAST.

Sand-blasting and painting Niagara Railway Arch Bridge. 1990.

SEWAGE DISPOSAL.

"Sewage and Wastes Disposal for the United States Army." Leonard S. Doten. 337. Discussion: Leonard Metcalf, Nicholas S. Hill, Jr., Almon L. Fales, Kenneth Allen, G. Bertram Kershaw, Edmund B. Besselievre, George T. Hammond, A. L. Sherman, J. F. Brown, and Lynn E. Perry. 353.

SILT.

"Notes on Tunnel Lining for Soft Ground." S. Johannesson and B. H. M. Hewett. (With Discussion.) 1822.

"The — Problem of the Zuni Reservoir." H. F. Robinson. (With Discussion.) 868.

SOILS.

Measurement of pressures transmitted through granular matter by the soil pressure cell. 1763.

STEEL.

"The Economics of — Arch Bridges." J. A. L. Waddell. (With Discussion.) 1.

STRAIN.

"Final Report of the Special Committee on Steel Columns and Struts." (With Discussion.) 1583.

"On a New Principle in the Theory of Structures." George F. Swain. (With Discussion.) 622.

STRAIN GAUGES.

See **EXTENSOMETERS.**

STRESS.

"Final Report of the Special Committee on Steel Columns and Struts." (With Discussion.) 1583.

Measurements of stresses by strain gauges. 1947.

"On a New Principle in the Theory of Structures." George F. Swain. (With Discussion.) 622.

"Revision of the Niagara Railway Arch Bridge." Charles Evan Fowler. (With Discussion.) 1919.

"Second Progress Report of the Special Committee to Report on Stresses in Railroad Track." (With Discussion.) 1409.

— in tunnnel lining. 460.

Stresses in arched dams. 2034.

Stresses in tunnel linings. 1824, 1830.

Unit stresses used in revision of Niagara Railway Arch Bridge. 1956.

SUSPENSION BRIDGES.

"A Simple Method of Computing Deflections of a Cable Span Carrying Multiple Loads Evenly Spaced." F. C. Carstarphen. (With Discussion.) 1383.

TEMPERATURE.

Effects of — on concrete in arch dams. 590.

TESTING MACHINES.

Description of Emery testing machine at Bureau of Standards, Washington, D. C. 1584.

TIMBER.

Tests of Guatemalian woods. 1695.

TOLUOL.

"The Production of — from Gas Plants." Myron S. Falk. 904. Discussion: A. C. Klein, and Horace C. Porter. 923.

TRACK.

"Second Progress Report of the Special Committee to Report on Stresses in Railroad — ." (With Discussion.) 1409.

TRAFFIC.

Daily vehicular — count over East River bridges. 436.

TRANSPIRATION.

"The Duty of Water in the Pacific Northwest." J. C. Stevens. (With Discussion.) 2094.

— for various standard crops. 224, 258.

TRANSPORTATION.

"The 'Light Railways' of the Battle Front in France." Frank G. Jonah. (With Discussion.) 1220.

TUNNEL SHIELDS.

— for proposed New York-New Jersey vehicular tunnel. 443.

TUNNELS.

"Grouting Operations, Catskill Water Supply." James F. Sanborn and M. E. Zipser. (With Discussion.) 980.

"Notes on Tunnel Lining for Soft Ground." S. Johannesson and B. H. M. Hewett. 1822. Discussion: J. C. Meem, E. G. Haines, Philip Aylett, Walter C. Parmley, C. M. Holland, T. Kennard Thomson, and Orrin L. Brodie. 1856.

Stress in tunnel lining. 460.

Stresses in tunnel linings. 1824, 1830.

"The Proposed New York and New Jersey Vehicular Tunnel." An Informal Discussion. Edward A. Byrne, John F. O'Rourke, Paul G. Brown, J. V. Davies, James Forgie, W. C. Parmley, T. Kennard Thomson, F. Lavis, Calvin Tomkins, Amos Schaeffer, and E. E. R. Tratman. 427.

TURBINES.

"Comprehensive Plotting of Water Turbine Characteristics." Karl R. Kennison. 861.

"Pressures in Penstocks Caused by the Gradual Closing of Turbine Gates." Norman R. Gibson. (With Discussion.) 707.

VALUATION.

"The Prospective Competitor Method of — of Property." M. L. Byers. 1313. Discussion: J. P. Snow, C. E. Grunsky, Joseph Mayer, J. E. Willoughby, and R. W. Hawley. 1360.

WATER, CONSUMPTION OF.

— in army camps. 509.

WATER, DUTY OF.

"Determination of the Duty of Water by Analytical Experiment." W. C. Hammatt. (With Discussion.) 200.

"The Duty of Water in the Pacific Northwest." J. C. Stevens. (With Discussion.) 2094.

WATER, FLOW OF, IN OPEN CHANNELS.

"Experiments on the Flow of Water Through Contractions in an Open Channel." E. W. Lane. 1149. Discussion: William T. Lyle, D. C. Henny, Karl R. Kennison, and R. D. Goodrich. 1209.

"Physiography of Water-Sheds and Channels, and Analysis of Stream Action of Southern California Rivers, with Reference to the Problems of Flood Control." A. L. Sonderegger. (With Discussion.) 1111.

WATER, FLOW OF, IN PIPES.

"Pressures in Penstocks Caused by the Gradual Closing of Turbine Gates." Norman R. Gibson. (With Discussion.) 707.

WATER, FLOW OF, OVER DAMS AND WEIRS.

"Verification of the Bazin Weir Formula by Hydro-Chemical Gaugings." Floyd A. Nagler. 105. Discussion: Clemens Herschel, David A. Molitor, Frederic P. Stearns, and B. F. Groat. 157.

WATER HAMMER.

"Pressures in Penstocks Caused by the Gradual Closing of Turbine Gates." Norman R. Gibson. (With Discussion.) 707.

WATER-LEVEL RECORDERS.

"The Accuracy of — and Indicators of the Float Type." J. C. Stevens. 894.

WATER MAINS.

See **PIPE.**

WATER PIPES.

See **PIPE.**

WATER PRESSURES.

"Pressures in Penstocks Caused by the Gradual Closing of Turbine Gates." Norman R. Gibson. (With Discussion.) 707.

WATER-WORKS.

"Grouting Operations, Catskill Water Supply." James F. Sanborn and M. E. Zipser. (With Discussion.) 980.

"Water Supply for the Camps, Cantonments, and Other Projects Built by the Construction Division of the United States Army." Dabney H. Maury. 481. Discussion: George W. Fuller, P. H. Norcross, Clarence Goldsmith, T. Kennard Thomson, W. P. Mason, J. Waldo Smith, E. T. Thurston, K. M. Boorman, William J. Boucher, Morris Knowles, H. F. Dunham, George A. Johnson, F. R. Harris, Maurice R. Scharff, Samuel A. Greeley, Lynn E. Perry, and Asa E. Phillips. 517.

WORLD WAR.

"The 'Light Railways' of the Battle Front in France." Frank G. Jonah. (With Discussion.) 1220.

AUTHOR INDEX

AFRICA, JAMES MURRAY.
Memoir of. 2139.

ALEXANDER, EDWARD PORTER.
Memoir of. 2414.

ALLEN, HERMON CHARLES.
Memoir of. 2141.

ALLEN, KENNETH.
Sewage and wastes disposal for the U. S. Army. 359.

AMMANN, O. H.
Revision of Niagara Railway Arch Bridge. 2000.

ANDERSON, J. T. NOBLE.
Pressures in penstocks. 764.

ANNEAR, EDGAR HAROLD.
Memoir of. 2353.

ARCHER, WILLIAM.
Memoir of. 2143.

ASPINWALL, THOMAS.
Memoir of. 2144.

ATWOOD, JOHN ABIEL.
Memoir of. 2145.

AYLETT, PHILIP.
Notes on tunnel lining. 1875.

BAKER, HOLLAND WILLIAMS.
Memoir of. 2147.

BALDWIN, A. S.
"Second Progress Report of the Special Committee to Report on Stresses in Railroad Track." 1409.

BAUM, F. G.
Contracts: "Cost plus" and other forms. 821.

BELL, ALONZO CLARENCE.
Memoir of. 2149.

BELL, VICTOR HUGO.
Memoir of. 2415.

BELLAMY, HERBERT E.
East Canyon Creek Dam. 612.

BELZNER, THEODORE.
Grouting operations. 1078.
Revision of Niagara Railway Arch Bridge. 2004.

BENTHAM, C.
Revision of Niagara Railway Arch Bridge. 2002.

BERGER, BERNT.
Memoir of. 2355.

BERNHARD, JOHN H.
National railroad question of to-day. 958.

BESSELIEVRE, EDMUND B.
Sewage and wastes disposal for the U. S. Army. 364.

BINCKLEY, GEORGE SYDNEY.
Hydraulic-fill dams. 1786.

BLACK, WILLIAM M.
Light railways of the battle front. 1241.

BLACKWELL, PAUL A.
Economics of steel arch bridges. 42.

BOORMAN, K. M.
Water supply for camps, cantonments, etc. 524.

BOUCHER, WILLIAM J.
Water supply for camps, cantonments, etc. 526.

BOVYER, WILLIAM BLAIR.
Memoir of. 2357.

BOWEN, EDWARD R.
Cement joints for cast-iron water mains. 302.

BOWLUS, FRED D.
Physiography of water-sheds and channels. 1143.

BOWMAN, AUSTIN LORD.
Memoir of. 2150.

BRAINARD, OWEN.
Memoir of. 2154.

BREED, H. ELTINGE.
American highways. 556.

BREMNER, G. H.
"Second Progress Report of the Special Committee to Report on Stresses in Railroad Tracks." 1409.

BRIGGS, WALDO C.
Grouting operations. 1069.

BRIGHT, CHARLES EDWIN.
Memoir of. 2358.

BRODIE, ORRIN L.
Notes on tunnel lining. 1905.

BROOKS, FREDERICK.
Memoir of. 2157.

BROWN, J. F.
Sewage and wastes disposal for the U. S. Army. 381.

BROWN, PAUL G.
Proposed New York and New Jersey Vehicular Tunnel. 452.

BROWN, RALPH HENRY.
Memoir of. 2159.

BROWN, STEPHEN PEARSON.
Memoir of. 2161.

BROWNE, WILLIAM LYON.
Memoir of. 2163.

BRUNNER, JOHN.
"Second Progress Report of the Special Committee to Report on Stresses in Railroad Track." 1409.

BRYSON, ANDREW.
Memoir of. 2165.

BUEL, A. W.
Guatemala earthquakes. 1706.
Stresses in railroad track. 1581.

BURR, WILLIAM H.
Hydraulic-fill dams. 1775.
New principle in the theory of structures. 676.
Steel columns and struts. 1648.
